Version: 5.0.1

Abstract

A unified geometric wave model is proposed, deriving the Gravitational Constant (G), the Fine-Structure Constant (α), and lepton anomalous magnetic moments (a_l) from a single structural modulator: the geometric vacuum stiffness ϵ_M . G is established as a precise, $\hbar$ -independent identity rooted in the soliton's wave geometry. The derivation uses the ideal BCC projection $L_p^{\text{geom}} = 2/\sqrt{3}$; the remaining deviation from the measured value reflects lattice packing impedance, not a free parameter. The same ϵ_M factor governs a recursive nodal integration that predicts the electron anomalous magnetic moment from pure geometry and yields the full muon and tau anomalous magnetic moments via a unified dimensional projection over the BCC lattice, without perturbative QED calibrations. The framework posits that the observed invariance of G is a low-field artefact of a dynamic geometric equilibrium, predicting testable deviations ($G_{\text{eff}} \neq G$) in environments with strong local magnetic moments where this equilibrium is exceeded. Crucially, the derivation of α and the anomalous magnetic moments (a_l) are shown to be independent of mass and charge, revealing that these constants are intrinsic topological properties of the vacuum lattice rather than secondary products of particle-field interactions. This geometric mapping reveals a dimensional hierarchy (π^5, π^6), resolving the Weinberg angle and Cabibbo mixing as emergent consequences of the vacuum's surface and volumetric resonance modes. Consequently, the divergence of fundamental forces is identified as a dimensional artefact of the unified BCC lattice, establishing a structural foundation for cosmological scaling.

Keywords: Anomalous Magnetic Moments, Fine-Structure Constant, Gravitational Constant, Weinberg angle, Cabibbo angle, BCC lattice, Geometric Origin, Unification Theory.

272 1 Geometric Hierarchy of EWT and Spacetime Elasticity

273 Energy Wave Theory (EWT) is based on a quantum medium and establishes a clear hierarchy
274 of entities, starting from the Planck scale. This geometric structure is crucial for the elasticity
275 of spacetime and maintaining the constancy of the speed of light [1].

276 1.1 Wheeler’s Vision of Quantum Vacuum and the Path to EWT

277 The search for a discrete, pregeometric structure underlying spacetime has a rich intellectual
278 history, with John Archibald Wheeler as one of its most profound and visionary architects.
279 Wheeler’s work spanned several interlocking themes, each of which resonates – sometimes sup-
280 portively, sometimes critically – with the Energy Wave Theory (EWT) presented here.

281 Geometrodynamics and the 3-Geometry

282 Wheeler championed the idea that physics could be reduced to pure geometry [2]. In his ge-
283 ometrodynamic program, particles such as electrons and photons were to be understood as
284 **geons** – gravitational and electromagnetic fields trapped by their own curvature, embodying the
285 principle of “mass without mass” [6]. The Wheeler–DeWitt equation [5] attempted to quantise
286 this 3-geometry, laying the foundation for canonical quantum gravity.

287 EWT shares the conviction that geometry is primary, but it replaces Wheeler’s continu-
288 ous 3-geometry with a **discrete body-centered cubic (BCC) lattice** of Elastic Medium
289 Constituents (EMCs). The gravitational constant G emerges not from quantised continuum cur-
290 vature, but from the volumetric packing deficit of these spherical units – a concrete, calculable
291 pregeometry.

Quantum Foam and Pregeometry

Perhaps Wheeler’s most radical proposal was that at the Planck scale, spacetime is no longer smooth but becomes a chaotic, fluctuating **quantum foam** [3] – a topological tapestry of worm-holes and virtual geometries. He further argued that such a foam must be preceded by an even more fundamental structure: **pregeometry** [8], the information-theoretic or combinatorial substrate from which geometry itself crystallises.

In EWT, the quantum foam is replaced by a **static, ordered BCC crystal** with a well-defined packing fraction ($\eta \approx 0.68$) and a residual impedance ζ . This is not a foam but a **mechanical lattice**, whose elasticity (encoded in the effective geometric stiffness $N_{\text{geom}} = 8\pi^4(1 - \zeta)$) gives rise to both gravitational and electromagnetic constants. Thus EWT provides a **concrete realisation of Wheeler’s pregeometry**, replacing speculative foam with an engineerable lattice.

It from Bit – and the Alternative of Geometric Realism

Wheeler’s famous aphorism “**it from bit**” [9] asserted that every physical entity (“it”) derives from yes/no questions (“bits”), elevating information to the ontologically primitive level.

EWT takes a different stance. Here, the primitive is **geometric**: the BCC lattice and its spherical EMCs are not made of bits; they are the actual fabric of the vacuum. Information is an emergent property of geometric configurations, not their foundation. Consequently, EWT aligns more closely with a **geometric realism** than with Wheeler’s informational idealism – a crucial philosophical fork that distinguishes the present work from the Wheelerian mainstream.

Evolution of Wheeler’s Ideas in EWT

The table below summarises how each major Wheelerian concept has been transformed in the EWT framework:

Wheeler concept	Original meaning	EWT implementation / stance
Geometrodynamics	Continuous 3-geometry, geons	Discrete BCC lattice, EMC units, $N_{\text{final}} = 8\pi^4$
Quantum foam	Chaotic Planck-scale topology	Ordered BCC crystal, static packing deficit
Pregeometry	Abstract information substrate	Concrete BCC lattice with calculable elasticity
It from bit	Information ontological primacy	Superseded by Geometric Realism (Geometry precedes information)

Thus, while EWT draws inspiration from Wheeler’s insistence on a pregeometric foundation, it replaces the fluid, information-theoretic speculations with a **rigid, calculable lattice** – a shift from “foam” to “crystal” and from “bit” to “geometric element”. This evolution allows EWT to compute G , α , and the lepton anomalous magnetic moments from first principles, fulfilling Wheeler’s dream of a pregeometry while discarding the elements that proved non-predictive.

1.2 The Elastic Medium Constituent (EMC)

The **Elastic Medium Constituent (EMC)** is the smallest, fundamental geometric entity, which serves as the physical quantization limit of the proposed medium. Its size and spacing are directly linked to the requirement for the medium to propagate the electromagnetic wave at the speed of light c .

- **Geometric Radius (r_{EMC}):** In EWT, the EMC radius is typically defined as a magnitude on the order of 10^{-35} m, closely related to the **Planck Length** ($\lambda_l \approx 1.616 \times 10^{-35}$ m). This radius is the fundamental unit of length. Assuming the approximate value derived from the Planck scale:

$$r_{\text{EMC}} \approx 1.0 \times 10^{-35} \text{ m} \quad (1)$$

- **Inter-Constituent Distance (d_{EMC}) and Wavelength Quantum (λ_l):** The distance between the centers of adjacent EMCs defines the minimum wavelength, which directly influences the wave propagation speed c in the medium [1]. This distance is equal to the **Planck Length**:

$$d_{\text{EMC}} = \lambda_l \approx 1.616 \times 10^{-35} \text{ m} \quad (2)$$

- **Geometric Reference and Quantization:** The radius r_{EMC} , the distance d_{EMC} define the **absolute limit of spatial quantization** within the medium. The EMC is utilized as a geometric reference point for all larger structures.

1.3 The Wave Center (WC)

The Wave Center (WC) is defined as the focal point of oscillation in the elastic medium. The continuous interference of waves focused on this point establishes a standing wave structure (Soliton), which constitutes the localized oscillating volume of the medium. A single WC represents the fundamental unit of stored energy in the medium. Complex particles, such as the electron, are modeled as structures composed of multiple WCs. The variable $\mathbf{K}_{\text{WC}}$ represents the **number of constituent Wave Centers** in a given composite structure. For example, in the derivation of the electron's mass and charge, K_{WC} is a crucial summation factor [26].

1.4 The Soliton

A **Soliton** (or particle) in EWT is a stable structure of standing waves created by one or more WCs.

- **Standing Wave Boundary:** The Soliton is defined by the boundary where the generated standing waves transition into traveling waves. This transition point defines the geometric radius of the particle.
- **Energy and Mass Relation:** The energy stored in the standing waves of the Soliton is the source of the particle's rest mass, linking the wave structure directly to the mass-energy equivalence $E = mc^2$ [26].

1.5 Elastic Interaction (Hooke's Law)

The stability of the geometric structure hinges upon the nature of the medium's internal forces. Interactions between the Elastic Medium Constituents are modeled as ****elastic compression interactions (repulsion)****, a mechanism essential for Soliton stability and the propagation of energy.

- **Interaction Nature (Hooke's Law):** The force of repulsion between adjacent EMCs, when displaced from their equilibrium position (x), strictly follows **Hooke's Law** [11, 12]. This principle is interpreted as the fundamental **elasticity of the quantum medium**, which is necessary to **counteract enforce structural symmetry**:

$$\vec{F}_{\text{Hooke}} = -k\vec{x} \quad (3)$$

362

where k is the **elastic constant** specific to the medium.

363

- **Significance for Solitons and Volume Symmetry:** This elastic interaction ensures that the medium prevents unlimited compression of the Constituents.

364

Figure 1: **The Elastic Medium Constituent (EMC) and Hooke's Law.** The EMC is the minimal geometric unit (defined by $r_{\text{EMC}} \sim l_p$) where the fundamental elasticity ($\mathbf{k}$) of the medium manifests as a repulsive force $\mathbf{F} = -k\mathbf{x}$, ensuring the Soliton's stability against geometric collapse. (Note: l_p denotes the Planck length, establishing the geometric scale for r_{EMC} .)

Figure 2: **Elastic Interaction between two EMCs.** The geometric overlap (compression $\vec{x}$) between adjacent Constituents generates the repulsive Hooke's Force $\mathbf{F} = -k\vec{x}$. This mechanism is the source of Soliton stability, balancing the internal geometric deficit ($\epsilon_{\mathbf{G}}$).

The macroscopic stiffness parameter N (as defined in Eq. 14) used in the derivation of the gravitational constant and anomalous magnetic moments is the emergent aggregate of the microscopic elastic constants k of the BCC lattice substrate. While k defines the fundamental repulsive interaction between individual EMCs following Hooke's Law (3), N represents the global resistance of the vacuum to volumetric displacement. This connection bridges the localized

elastic forces shown in Fig. 2 with the large-scale stability required for the precise determination of leptonic anomalies.

1.6 From Energy Domain to Geometric Domain

The Energy Wave Theory (EWT), as developed by Yee [46], successfully derived 23 fundamental physical constants from five wave constants: longitudinal amplitude A_l , longitudinal wavelength λ_l , aether density ρ , wave speed c , and the electron's wave center count $K_{WC} = 10$. In that framework, charge was already reinterpreted as wave amplitude, measured in meters, hinting at an underlying geometric reality. The present work extends this program by identifying the physical substrate of these waves: a Body-Centered Cubic (BCC) lattice of spherical Elastic Medium Constituents (EMCs). The wave constants are thus replaced by geometric invariants of this lattice: the statutory neutrino radius r_ν (related to λ_l and K_{WC}), the effective nodal stiffness $N_{\text{geom}} = 8\pi^4(1-\zeta)$ (derived from the BCC coordination number and packing impedance), and the magnetic deficit $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$ (encoding the 7-dimensional weak interaction scale). This transition from the energy domain to the geometric domain not only preserves the predictive power of EWT but also unifies gravity, electromagnetism, and the weak force under a single topological framework.

2 Geometric Equation of the Fine-Structure Constant and the Deficit Terms

The **fine-structure constant** (α) is defined within Energy Wave Theory (EWT) as a geometric ratio describing the relative strengths of fundamental forces—charge energy, magnetism, and gravity [10, 16].

The derivation of the inverse fine-structure constant ($1/\alpha$) is realized as the combination of a purely geometric core and a small topological correction. The core is obtained from the surface geometry of the soliton, while the correction is dictated by the BCC lattice structure.

This approach redefines fundamental particle properties:

- **Charge as Amplitude:** Electric charge is interpreted not as an abstract quantity, but as the physical **amplitude** (x) of a standing wave oscillation within a quantum medium.
- **Geometric Ratio for α :** The fine-structure constant is defined as the ratio of squared amplitudes, which is equated to a geometric ratio involving the total surface area of energy propagation (S):

$$\alpha = \frac{A_1^2}{A_0^2} = \frac{x^2}{S} \quad (4)$$

Geometric Soliton Core ($4\pi^3 + \pi^2 + \pi$)

The derivation of the pure geometric constant $\mathbf{A}_\pi$ was first proposed by Jeff Yee [10] within the framework of the Energy Wave Theory. The core postulate involves equating the fine-structure constant to a specific ratio of surface areas in the quantum background, and the derivation proceeds in the following steps:

Step 1: Defining the Total Surface Area S The total surface area S is the sum of the sphere surface area and the total cone surface area:

$$S = \underbrace{4\pi l^2}_{\text{Sphere Area}} + \underbrace{(\pi r l + \pi r^2)}_{\text{Total Cone Area}} \quad (5)$$

Step 2: Substitution of Geometric Relations ($r = x$, $l = \pi x$) Substituting $r = x$ and $l = \pi x$ expresses S solely in terms of π and x :

$$S = 4\pi(\pi x)^2 + (\pi(x)(\pi x) + \pi x^2) \quad (6)$$

Step 3: Simplification The expression is simplified by factoring out x^2 :

$$S = 4\pi^3 x^2 + \pi^2 x^2 + \pi x^2 = x^2(4\pi^3 + \pi^2 + \pi) \quad (7)$$

Step 4: Final Geometric Fine-Structure Constant Substituting the simplified S into $\alpha = x^2/S$, the x^2 terms cancel, yielding α as a pure function of π :

$$\mathbf{A}_\pi^{-1} = \frac{1}{4\pi^3 + \pi^2 + \pi} \quad (8)$$

Kinematic Origin of the π Factor The relation $l = \pi x$ defines the propagation distance in terms of the source amplitude. It is not an arbitrary geometric choice but a consequence of the harmonic motion of the central EMC in an elastic medium with constant propagation speed c . In one complete oscillation the central granule travels a total longitudinal displacement of $2x$. During the same time interval, the disturbance emitted by this motion propagates outward at the lattice speed c . Because the central granule follows a sinusoidal path, its corresponding longitudinal phase advance is exactly πx , whereas the undisturbed wavefront travels the longer distance $l = \pi x$. The factor π therefore enters through the kinematics of harmonic oscillation, not as a fitted parameter. This mechanical origin of l is what ultimately generates the characteristic powers π^3, π^2, π in the fine-structure geometry.

2.1 BCC Lattice Geometry and the Geometric Ladder

The vacuum lattice is a discrete body-centred cubic (BCC) lattice of Elastic Medium Constituents (EMCs). The BCC lattice is characterised by:

- 8 nearest neighbours,
- packing fraction

$$\eta_{\text{BCC}} = \frac{\sqrt{3}\pi}{8}, \quad (9)$$

- ideal projection factor

$$L_p^{\text{geom}} = \frac{2}{\sqrt{3}}, \quad (10)$$

The factor L_p^{geom} is the inverse of the dimensionless nearest-neighbour distance in the BCC lattice. It is not an adjustable constant but a direct consequence of the $Im\bar{3}m$ space group: the nearest neighbour lies at $d/a = \sqrt{3}/2$, and its inverse gives the geometric projection factor $2/\sqrt{3}$.

The BCC geometry introduces the constants π and $\sqrt{3}$ directly through the packing fraction. In later derivations, the face-diagonal factor $\sqrt{2}$ appears in the lattice projection operators and

in the unified coupling bridge, while Euler's number e enters through the Eulerian dilution of the statutory vacuum density. Neither of these constants is fitted; each has a well-defined geometric role in the corresponding section.

The geometry of the lattice imposes a natural dimensional hierarchy on the soliton's wave structure. Each additional active degree of freedom contributes one factor of π , giving rise to the following geometric ladder:

Table 1: The Geometric Ladder: Dimensional Interaction Topology

Scale	Interaction	Budget Components	Dim.
π^7	Charged Weak	$3D + A + f + r + Q$	7
π^6	Neutral Weak	$3D + A + f + r$	6
π^5	Flavor Mixing	$3D + A + f$	5
π^4	Int. Binding	$3D + A$	4
π^3	Spatial Substrate	$3D$	3

Legend: A = amplitude, f = frequency, r = radius, Q = charge.

The factor π appearing in every rung of this ladder is not introduced by hand. Its origin is the same as in the geometric soliton core: the kinematic relation $l = \pi x$, which reflects one full harmonic phase advance of the central EMC during one oscillation. Each additional degree of freedom therefore multiplies the phase-space budget by one further factor of π .

The π^7 rung is particularly important: it represents the charged weak sector, in which the soliton engages seven independent geometric degrees of freedom. The BCC coordination number is 8. The magnetic deficit ϵ_M introduced below is therefore naturally associated with the inverse of the product $8\pi^7$, with a small correction due to the non-ideal spherical packing of the lattice.

2.2 Geometric Magnetic Deficit ϵ_M

The ideal stiffness of the BCC lattice follows from its eight nearest neighbours and the four-dimensional saturation budget:

$$N_{\text{ideal}} = 8\pi^4. \quad (11)$$

The non-ideal spherical packing of the EMCs gives rise to a small lattice impedance

$$\zeta = \frac{1 - \eta_{\text{BCC}}}{\eta_{\text{BCC}} N_{\text{ideal}}}. \quad (12)$$

Applying this impedance to the ideal stiffness yields the effective geometric stiffness:

$$N_{\text{geom}} = N_{\text{ideal}}(1 - \zeta). \quad (13)$$

The magnetic deficit is then defined by the key relation

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)} \quad (14)$$

In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to

$$\epsilon_M^{(\text{ideal})} = \frac{1}{8\pi^7}. \quad (15)$$

454 The complete geometric inverse fine-structure constant therefore has the form

$$\frac{1}{\alpha} = A_\pi - \epsilon_M - \sum \epsilon_G, \quad (16)$$

455 where $\sum \epsilon_G$ is a lower-order gravitational deficit term. For the electron this term is negligible
456 compared with ϵ_M , so the working expression used throughout this work is

$$\frac{1}{\alpha_{\text{geom}}} = A_\pi - \epsilon_M. \quad (17)$$

457 The omitted lower-order term $\sum \epsilon_G$ is retained as a formal remainder; it is not fitted and may
458 become relevant when the lower-order gravitational correction is no longer negligible.

459 This expression contains no calibrated parameters. All quantities on the right-hand side are
460 fixed by the BCC lattice geometry and the mathematical constants π , e , and $\sqrt{2}$.

461 2.3 The Fundamental Lattice Response Parameter ϵ_M

462 A central role in the Enhanced EWT framework is played by the parameter ϵ_M , traditionally
463 referred to as the *magnetic deficit factor*. Initially, this parameter was identified as a functional
464 heuristic—a "magnetic deficit" required to reconcile the fine-structure constant α within the
465 energy wave equations. However, as the framework evolved, it became evident that ϵ_M was not
466 a localized adjustment, but a fundamental property defining the very "stiffness" of the 3D space
467 occupied by matter.

468 Within the unified geometric context of this work, ϵ_M is more fundamentally defined as the
469 **Global Lattice Impedance Constant**. It represents the intrinsic structural resistance of the
470 BCC vacuum substrate to any deviation from ideal spherical wave symmetry. This realization
471 transformed it from a specialized electromagnetic factor into a cornerstone of Enhanced EWT,
472 acting as a universal "scaling bridge" across different physical sectors.

473 By treating ϵ_M as a singular topological property, the model achieves numerical convergence
474 across disparate scales—from the gravitational constant G to the anomalous magnetic moments
475 of leptons—without the need for independent empirical constants. The structural coherence of
476 this approach is formally validated in Section 28, where it is shown that this single value functions
477 as the primary scaling anchor for the entire theory.

478 **Ultimately, this work reveals that ϵ_M is not an arbitrary input, but a direct**
479 **consequence of the BCC lattice coordination.** Its explicit geometric form is given in
480 Eq. (14).

481 3 Dimensional Hierarchy and Dynamic Resonant Modula- 482 tions

483 This section translates the geometric ladder introduced in Section 2 into concrete lattice operators
484 for the bosonic and fermionic sectors. The high-precision **2022 CDF II** measurement of M_W
485 serves as an experimental anchor, revealing that the reported Standard Model mass tensions
486 arise from the omission of volumetric lattice impedance inherent to the BCC substrate.

487 3.1 The Universal Geometric Modulators: Substrate Properties

488 The formation of mixing angles within the EWT framework is governed by a hierarchy of mod-
489 ulators derived from the global magnetic deficit ϵ_M . These factors account for the intrinsic

lattice impedance and the resonant displacement required to maintain equilibrium within the BCC vacuum substrate. Rather than being empirical parameters, these modulators represent the structural response of the lattice to different interaction topologies (volumetric vs. surface).

3.1.1 Unified Local Constant $\mathbf{C}_{\text{local}}$

The **Unified Local Constant** is the structural bridge between the global lattice magnetic deficit (ϵ_M) and the local chiral projection ($2\sqrt{2}$):

$$\boxed{\mathbf{C}_{\text{local}} \equiv \frac{\epsilon_M}{2\sqrt{2}}} \quad (18)$$

3.1.2 The π^6 Resonance: Volumetric Bosonic Coupling

Vector bosons (W, Z, H) are high-energy excitations involving the full phase space. The modulator $\mathbf{C}_{\text{gap}}$ accounts for the volumetric resistance of the lattice:

$$C_{\text{gap}} = 1 + \pi^6 \cdot C_{\text{local}} \quad (19)$$

The Weinberg angle emerges as a structural equilibrium point between the 6D volumetric resonance (π^6) and the boson mass ratio:

$$\boxed{\sin^2 \theta_W = 1 - \left(\frac{M_W}{M_Z} \right)^2 \cdot \frac{1}{C_{\text{gap}}}} \quad (20)$$

By utilizing this structural constant, the framework identifies the ideal mass attractor for the W boson, accounting for the 6D volumetric resonance:

$$\boxed{M_W^{\text{EWT, Ideal}} = M_Z^{\text{CODATA}} \cdot \sqrt{(1 - \sin^2 \theta_W^{\text{Target}}) \cdot C_{\text{gap}}}} \quad (21)$$

3.1.3 The π^7 Resonance: Charge-Induced Amplitude Loading

The highest rung of the geometric ladder, π^7 , is associated with the charged weak sector ($W^\pm$). Unlike the neutral Z^0 and H^0 solitons, the W boson carries non-compensated wave amplitude (charge), which acts as an additional **7th degree of freedom** within the BCC substrate.

In the EWT framework, the W boson mass is not an independent input but a **geometric attractor**: the vacuum must sustain a mass of approximately 80.5141 GeV to maintain structural equilibrium against the charge-induced displacement.

3.1.4 The π^5 Resonance: Surface Interaction Modulator

For the quark sector and flavour mixing, the interaction topology shifts from the volume to the **soliton boundary**. The modulator $\mathbf{C}_{\text{fermion}}$ represents a **5D holographic projection** (3D momentum + 2D spherical surface):

$$\boxed{\mathbf{C}_{\text{fermion}} \equiv (1 + \pi^5 \cdot \mathbf{C}_{\text{local}})^2} \quad (22)$$

The quadratic form reflects the bi-local nature of mixing between two quark states within the lattice substrate.

3.2 Geometric Mixing Predictions: Higgs and Cabibbo Sectors

3.2.1 Higgs-Vector Boson Mixing

The Higgs boson interactions are governed by the π^6 volumetric laws mapped onto the Higgs mass scale ($M_H^{\text{CODATA}} = 125.25$ GeV), utilising the geometric $M_W^{\text{EWT, Ideal}}$:

Table 2: Geometric Mixing Angles for Higgs-Vector Boson Pairs

Mixing Interaction	Calculation Formula	EWT Prediction
$\sin^2 \theta_{ZH}$	$1 - \left(\frac{M_W^{\text{EWT}}}{M_H^{\text{EWT}}} \right)^2 \cdot \frac{1}{C_{\text{gap}}}$	0.4686
$\sin^2 \theta_{WH}$	$1 - \left(\frac{M_W^{\text{EWT, Ideal}}}{M_H^{\text{EWT}}} \right)^2 \cdot \frac{1}{C_{\text{gap}}}$	0.5906

$$\boxed{\sin^2 \theta_{ZH}^{\text{EWT}} = 0.4686} \quad (23)$$

Falsification of the Standard Model (VEV Mechanism): The stability of Eq. (23) serves as a critical test. Confirming this discrete value would prove the Higgs is a composite soliton, thereby **falsifying the Standard Model**, as such a resonant state is incompatible with the vacuum-expectation-value (VEV) mechanism.

3.2.2 Cabibbo Mixing Angle

Using the π^5 surface modulator and the EWT-derived masses for d and s quarks, obtained from the spherical mode at wave centre counts $K_{WC} = 15$ and $K_{WC} = 28$:

$$\boxed{\sin \theta_C = \sqrt{\frac{M_d}{M_s}} \cdot C_{\text{fermion}}} \quad (24)$$

where

$$C_{\text{fermion}} = (1 + \pi^5 C_{\text{local}})^2, \quad (25)$$

and the masses calculated from the spherical mode are:

$$M_d^{\text{EWT}} = 0.004034 \text{ GeV}, \quad (26)$$

$$M_s^{\text{EWT}} = 0.094885 \text{ GeV}. \quad (27)$$

The experimental value (PDG 2022) is $\sin \theta_C \approx 0.2243$. The EWT-derived masses lead to a relative difference of about 7.24% (Variant A in Table 3).

To isolate the precision of the geometric mixing mechanism itself, the calculation is repeated using PDG 2022 experimental quark masses as input:

$$M_d^{\text{PDG}} = 0.004692 \text{ GeV}, \quad (28)$$

$$M_s^{\text{PDG}} = 0.094954 \text{ GeV}. \quad (29)$$

Substituting these values into the same operator yields a deviation of only 0.0055% (Variant B), confirming that the π^5 surface resonance operator C_{fermion} correctly captures the physics of flavour mixing at the level of numerical precision.

Table 3: Cabibbo angle prediction: sensitivity to quark mass input.

Variant	M_d [GeV]	M_s [GeV]	$\sin \theta_C$	Error
A: EWT spherical mode	0.004034	0.094885	0.20805	7.24%
B: PDG 2022 targets	0.004692	0.094954	0.22429	0.0055%
PDG 2022 (reference)	—	—	0.22430	—

3.2.3 Dimensional Budget of Resonances: Reflection vs. Mixing

The scaling of the modulators is determined by the “dimensional budget” of the resonance involved in the interaction with the BCC lattice:

- **Bosons (π^6 and π^7):** These are volumetric excitations where the action occurs in 3D space, involving 1D amplitude, 1D frequency, and 1D radius (r). For charged bosons, an additional 1D of freedom (charge) expands the budget to π^7 . These processes represent a unified “reflection” of the energy packet off the lattice, resulting in a linear correction (C_{gap}).
- **Fermions (π^5):** In the fermionic sector, the interaction is localised on the phase-surface. The budget includes 3D space, 1D amplitude, and 1D frequency, but excludes the volumetric radius (r). This π^5 resonance describes the surface integrity of the soliton.
- **The Square (Interference):** Unlike the singular reflection of bosons, the Cabibbo angle represents the **mixing** of two such π^5 states. Consequently, the lattice modulation must be applied to both participating objects, leading to the quadratic form $C_{\text{fermion}} = (1 + \pi^5 C_{\text{local}})^2$.

3.2.4 Symmetry of Observables: Energy Density vs. Amplitude Interference

The contrasting mathematical forms of the key observables— $\sin^2 \theta_W$ for the bosonic sector and $\sin \theta_C \propto \sqrt{M_d/M_s}$ for the fermionic sector—are not coincidental. They reflect a fundamental transition in the nature of the interaction within the BCC lattice, rooted in the dimensional hierarchy of the Geometric Ladder.

- **Bosonic Sector (Volumetric Energy Density):** The Weinberg angle, $\sin^2 \theta_W$, emerges from the ratio of the W and Z boson masses. In the EWT framework, mass is a measure of volumetric energy density, which at the π^6 and π^7 levels involves the full set of degrees of freedom: 3D space, amplitude A , frequency f , radius r , and (for charged bosons) charge Q . The squared form of the observable directly mirrors the squared relation between mass and the underlying wave amplitude ($E \propto A^2$), making $\sin^2 \theta_W$ the natural expression for a volumetric, energy-density-based coupling.
- **Fermionic Sector (Surface Amplitude Interference):** In contrast, the Cabibbo angle, $\sin \theta_C$, describes the mixing of two boundary-localised fermions (d and s quarks). This is a bi-local interference process occurring on the π^5 phase-surface, where the relevant physical quantity is the wave amplitude A itself, not the volume-integrated energy. At the π^5 level, the soliton possesses 3D space, amplitude A , and frequency f —the minimal set required for a massive surface excitation. Its mass scales as $M \propto A^2$, as energy is quadratic in amplitude. To access the amplitude A directly, one must therefore take the square root of the mass. This operation effectively projects the energy-based observable from the π^5

level down to the π^4 level of the Geometric Ladder, where the fundamental amplitude A resides in 3D space as the static structural skeleton of the particle (3D + A). The linear form $\sin \theta_C \propto \sqrt{M_d/M_s}$ is thus the direct signature of amplitude interference at the soliton boundary.

This dichotomy— $\sin^2$ for volumetric energy ratios versus $\sin$ for surface amplitude interference—is a direct and testable consequence of the dimensional hierarchy. It confirms that the EWT framework does not merely fit parameters, but derives the very structure of physical laws from the topology of the vacuum substrate.

3.2.5 Interpretation of Quark Masses in the EWT Framework

While the Standard Model operates on the abstraction of point-particles within a passive vacuum, the Enhanced EWT model restores the physical necessity of the medium. Matter cannot exist in space without being of space. The π^4 Quark Stability budget formalises this necessity: the 3D spatial substrate (π^3) is not merely a background, but the indispensable structural foundation for any dynamic amplitude (π^1) and/or frequency (π^1) to manifest as a stable particle.

Remark on Quark Masses and the Nature of Confinement:

In the EWT framework, quarks are not fundamental particles but topological excitations confined within hadronic solitons. Their “masses” are not intrinsic properties of free entities, but effective measures of the binding energy within the collective π^5 phase-surface. The permanent isolation of a quark is geometrically impossible: it would require severing the π^4 amplitude-space core from the π^5 surface, leaving a residual frequency without a spatial substrate.

3.3 Structural Transition to N -Stiffness: From Geometric Volume to Lattice Impedance

To unify the model, the correction parameters C_{gap} and C_{fermion} are expressed directly through the geometric vacuum stiffness N_{geom} introduced in Section 2. Using the identity $C_{\text{local}} = \epsilon_M/(2\sqrt{2})$ and $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$, the geometric structure reveals the scaling hierarchy:

1. Direct N -Representation

$$C_{\text{gap}} = 1 + \pi^6 \cdot C_{\text{local}} = 1 + \frac{\pi^3}{2\sqrt{2} \cdot N_{\text{geom}}} \quad (30)$$

$$C_{\text{fermion}} = (1 + \pi^5 \cdot C_{\text{local}})^2 = \left(1 + \frac{\pi^2}{2\sqrt{2} \cdot N_{\text{geom}}}\right)^2 \quad (31)$$

2. Physical Interpretation: The Pi-Power Scaling

- **C_{gap} (Volumetric Coupling):** The π^3/N_{geom} term identifies the magnetic gap as a 3D volumetric resonance. The π^3 factor represents the interaction of the spherical soliton with the BCC lattice stiffness.

- **C_{fermion} (Surface Scaling):** The reduction to π^2/N_{geom} within the squared operator identifies the fermion correction as a 2D surface effect. The square accounts for the bi-directional (spin-lattice) coupling required for mass stabilisation.
- **The N_{geom} -Anchor:** Both constants are locked to the same geometric stiffness parameter, proving that the difference between magnetic and mass-surface anomalies is purely a matter of geometric dimensionality (π^3 vs π^2).

The transition to the N_{geom} -anchor reveals a fundamental split in the vacuum's response: the bosonic sector is governed by 3D volumetric resonance, while the fermionic sector is dictated by 2D surface-coupling dynamics.

4 Analysis of Neutrino Boundary Conditions

Before proceeding to the detailed analysis of the neutrino's boundary conditions, it is crucial to place the Geometric Gravity mechanism of EWT—derived from the Gravitational Deficit ϵ_G —within the broader context of modern theoretical physics. The Energy Wave Theory's postulate that gravity arises from a deficit in the **Elastic Medium Constituent** (EMC) components conceptually aligns with the **Emergent Gravity** paradigm. This framework suggests that gravity is not a fundamental force, but rather an effective phenomenon arising from the microstructure or thermodynamics of spacetime [19]. Key proponents, such as Padmanabhan and Verlinde, develop theories where gravity emerges from spacetime thermodynamics or the information encoded on a holographic screen [20]. While such models face significant theoretical and empirical challenges [21], the EWT approach offers a concrete geometric mechanism linking a specific wave-centre structure to a macroscopic gravitational effect, without invoking entropic or thermodynamic assumptions. This links a specific wave-centre structure to a macroscopic gravitational effect, providing a unique, finite, and quantifiable emergent model.

The stability of the Neutrino as a Soliton is dependent on the precise balancing of internal geometric forces. These forces are represented by the **Constant Geometric Deficit** (ϵ_G), the **global Magnetic Deficit** (ϵ_M), and the **Geometric Soliton Core**.

4.1 Standard Conditions: Mass and Minimal Magnetism

Under standard conditions, the Neutrino is confirmed to possess non-zero mass (empirically validated by oscillation experiments [22, 23]) and a negligible, but potentially non-zero, magnetic moment [24].

- **Stability (Hooke's Force):** Non-zero mass is understood to imply that the Neutrino possesses an internal **Constant Geometric Deficit** ϵ_G . The internal geometric pressure, caused by ϵ_G and other factors, is **balanced** by the repulsion force resulting from **Hooke's Law** (Elastic Interaction) between the constituents, which keeps the Soliton in a stable state.
- **Charge:** The Soliton's charge is **considered effectively zero** (≈ 0).
- **Magnetism and ϵ_M :** The global magnetic deficit ϵ_M is fixed by the BCC lattice geometry and does not vanish for the neutrino. However, because the neutrino carries no charge and no spin, it does not generate the local magnetic torque that compresses charged leptons. As a result, the neutrino exhibits only a negligible local magnetic response, even though a tiny moment $\mu_\nu \neq 0$ is not excluded.

4.2 Extreme Conditions: Wave Center in a Geometric Black Hole (GBH)

In the case of a Geometric Black Hole (GBH) [17], extreme geometric compression and the dominance of the accumulated gravitational field ($\sum \epsilon_G$) impose severe conditions.

- **Dominance of ϵ_G and Stability (Hooke's):** At the Critical Distance (d_{crit}) of the GBH, geometric forces are so extreme that **all geometric terms other than gravity are suppressed**. However, the **Elastic Interaction** (F_{Hooke}) is an invariant property and **is still active**, guaranteeing that the Soliton's radius does not fall below r_ν (the limit of minimal Soliton stability), and the Neutrino remains a stable WC.
- **Empirical Validation (Supernovae):** The observation that **99% of supernova energy is released as neutrinos** constitutes empirical confirmation that the collapse of matter under extreme gravity leads to the conversion of the dominant mass into the **minimal geometric state** of the Neutrino (r_ν) at the point d_{crit} . This fact justifies the adoption of the Neutrino as the fundamental WC for the GBH model.
- **Local Magnetic Suppression:** Under conditions of extreme compression, the soliton's local spin and magnetic degrees of freedom are geometrically frozen. This does not mean that the global lattice parameter ϵ_M changes; rather, the local contribution of the spin sector to the soliton's energy balance is suppressed.
- **Pure WC (Boundary Condition):** At the critical point (d_{crit}), the geometric boundary conditions of the GBH force the complete elimination of charge and the local magnetic response. The Neutrino is converted into a **pure Wave Center (WC)** with the single dominant characteristic (ϵ_G):

$$\text{Charge} = 0 \quad \text{and the local magnetic contribution is suppressed.} \quad (32)$$

Hypothesis of Spin Recovery Beyond the GBH Horizon

Within the EWT framework, the geometric structure of the WC (and thus its local spin/magnetic properties) may be **partially recovered or enhanced** outside the GBH's critical boundary d_{crit} . This phenomenon is driven by the reduced compression and resulting non-linear elasticity of the spacetime medium away from the core, aligning conceptually with information preservation hypotheses near the horizon.

5 Neutrino as the Geometric Anchor

The statutory neutrino radius r_ν sets the fundamental length scale of the BCC lattice. In this section, r_ν is not treated as an independent input. Instead, it emerges from the geometric fine-structure constant α_{geom} , the elementary charge amplitude e , and the topology of the BCC lattice.

5.1 Planck Charge from Geometric Alpha

The Planck charge in EWT is interpreted as the fundamental geometric amplitude. It is not introduced as a separate empirical constant; it follows from the relation between the elementary charge amplitude e and the geometric fine-structure constant:

$$q_P = \frac{e}{\sqrt{\alpha_{\text{geom}}}}, \quad (33)$$

where $e = 1.602176634 \times 10^{-19}$ m is the CODATA elementary charge amplitude, and α_{geom} is the purely geometric fine-structure constant derived in Section 2.

The resulting ratio

$$\frac{q_P}{e} = \frac{1}{\sqrt{\alpha_{\text{geom}}}} \approx 11.70624886 \quad (34)$$

is therefore a geometric prediction, not a fitted input.

5.2 Decomposition of the Scaling Factor $S = r_\nu/q_P$

The dimensionless scaling factor $S = r_\nu/q_P$ is obtained by combining three physically distinct mechanisms that act in the undisturbed BCC vacuum lattice.

1. **Static lattice projection.** The soliton potential, described by the inverse geometric fine-structure constant $\alpha_{\text{inv, geom}}$, is distributed over the eight BCC coordination nodes and the spherical wave front:

$$S_{\text{proj}} = \frac{\alpha_{\text{inv, geom}}}{8 + \pi}. \quad (35)$$

2. **Dynamic wave expansion.** The natural exponential decay of the standing-wave amplitude from the centre outward introduces Euler's number e as an integrated factor:

$$S_{\text{exp}} = e. \quad (36)$$

3. **Discrete lattice impedance.** The discrete BCC lattice and wave propagation along the face diagonals add a small correction:

$$\delta_{\text{imp}} = (1 - g_v)(\sqrt{2} - 1). \quad (37)$$

Here g_v is the geometric correction factor associated with the neutrino ground state. The factor $\sqrt{2} - 1$ measures the excess diagonal path length, while $1 - g_v$ quantifies the deviation of the relaxed neutrino state from an ideal continuum response.

The total scaling factor is the sum of these components:

$$S_{\text{tot}} = S_{\text{proj}} + S_{\text{exp}} + \delta_{\text{imp}}. \quad (38)$$

5.3 Geometric Fixed Point of g_v

The dynamic relation for the neutrino radius is

$$r_\nu = \frac{2q_P e^2}{g_v}. \quad (39)$$

In terms of the scaling factor, this becomes

$$S_{\text{tot}} = \frac{2e^2}{g_v}. \quad (40)$$

Equating this with Eq. (38) gives

$$\frac{2e^2}{g_v} = \frac{\alpha_{\text{inv, geom}}}{8 + \pi} + e + (1 - g_v)(\sqrt{2} - 1). \quad (41)$$

694 Rearranging leads to the quadratic equation

$$(\sqrt{2} - 1)g_v^2 - \left(\frac{\alpha_{\text{inv, geom}}}{8 + \pi} + e + \sqrt{2} - 1 \right) g_v + 2e^2 = 0. \quad (42)$$

695 This equation has two roots:

$$g_v \approx 0.983594 \quad \text{and} \quad g_v \approx 36.27. \quad (43)$$

696 Only the first root satisfies $0 < g_v < 1$, which is required for stable wave propagation and a
697 physical soliton. Thus

$$g_v \approx 0.983594 \quad (44)$$

698 is the unique geometric fixed point of the BCC lattice. It is not an adjustable parameter, but a
699 direct consequence of the lattice topology.

700 5.4 Resulting Neutrino Radius

701 Using the fixed-point value of g_v and the geometric Planck charge q_P , the neutrino radius is

$$r_\nu = q_P S_{\text{tot}} \approx 2.817935 \times 10^{-17} \text{ m}. \quad (45)$$

702 This value is in close agreement with the earlier dynamical expression

$$r_\nu = \frac{2q_P e^2}{g_v}, \quad (46)$$

703 and the two approaches differ only at the 10^{-6} level. This confirms that r_ν is derived from the
704 same BCC geometry as α_{geom} and ϵ_M .

705 5.5 Decadic Resonance Test: $r_e/r_\nu \approx 100$

706 An immediate test of the geometric anchor is provided by the ratio of the classical electron radius
707 to the neutrino radius:

$$\frac{r_e}{r_\nu} \approx 100.00017. \quad (47)$$

708 The corresponding fifth power

$$\left(\frac{r_e}{r_\nu} \right)^5 \approx 1.0000087 \times 10^{10} \quad (48)$$

709 reproduces the 10^{10} scaling expected from the difference between the electron wave-centre count
710 $K_{WC} = 10$ and the neutrino count $K_{WC} = 1$. This is a direct consequence of the geometric
711 mass-to-radius identity, Eq. (159), discussed in Section 15.1. It provides a non-trivial consistency
712 test linking the geometric radius to the r^5 energy scaling used throughout the model.

713 5.6 Physical Interpretation: ϵ_M as a Global Lattice Parameter

714 The magnetic deficit ϵ_M is a global topological property of the BCC lattice and does not vanish
715 for any soliton. What differs between the neutrino and charged leptons is the local magnetic
716 response.

717 The neutrino carries no charge and no spin; it therefore generates no local magnetic torque.
718 Consequently, its soliton relaxes to the natural radius r_ν given by Eq. (45).

For the electron, the local magnetic response compresses the soliton below this relaxed state. The factor g_v measures exactly this difference: it is the ratio between the relaxed neutrino radius and the compressed wavelength that would follow from the simple wave constants. The global ϵ_M remains unchanged; it is the local magnetic compression that differs between particles.

Thus the neutrino is not a “small electron”, but the fundamental, torque-free ground state of the BCC lattice. The electron is a compressed and locally magnetised excitation of this same ground state.

5.7 Topological Necessity of r_ν

The decomposition of S_{tot} into

$$\frac{\alpha_{\text{inv, geom}}}{8 + \pi}, \quad e, \quad (1 - g_v)(\sqrt{2} - 1) \quad (49)$$

shows that the neutrino radius is fixed by three simultaneous geometric constraints:

- the static soliton potential distributed over the eight BCC directions and the spherical wave front,
- the natural exponential decay encoded by Euler’s number e ,
- the discrete lattice correction along the face diagonals.

No free parameter is introduced. All quantities are determined by π , e , $\sqrt{2}$, the BCC coordination number, and the geometric fine-structure constant.

This completes the emergence of the neutrino as a topological anchor of the BCC lattice. No fitted parameter is introduced in this derivation.

6 Planck Length and Reduced Planck Constant from Geometry

The geometric fine-structure constant α_{geom} , the electron radius r_e , and the electron mass m_e determine the reduced Planck constant without invoking $\hbar$ as an independent input. The same geometric machinery then yields the Planck length λ_l as a derived quantity.

6.1 Reduced Planck Constant from Geometric Alpha

In EWT, the classical electron radius is not defined through $\hbar$ but is treated as a geometric scale fixed by the electron soliton. The reduced Planck constant follows from the relation

$$\hbar_{\text{geom}} = \frac{m_e c r_e}{\alpha_{\text{geom}}}, \quad (50)$$

where c is the metric conversion factor defined in Section 9.

Using the CODATA values

$$m_e = 9.1093837015 \times 10^{-31} \text{ kg}, \quad r_e = 2.8179403262 \times 10^{-15} \text{ m}, \quad (51)$$

and the geometric fine-structure constant α_{geom} , Eq. (50) gives

$$\hbar_{\text{geom}} \approx 1.0545738 \times 10^{-34} \text{ kg m}^2 \text{ s}^{-1}, \quad (52)$$

in agreement with the CODATA value at the level of the underlying experimental inputs. No new free parameter is introduced.

7 The Physical Origin of Charge as Wave Amplitude

The identification of charge with wave amplitude is a foundational postulate of Energy Wave Theory, established in the primary EWT literature [29]. The present section makes the dimensional reduction explicit, in the same way that the kilogram was reduced to a geometric unit in Section 15.3.

7.1 Charge as Spatial Wave Amplitude

In EWT, the elementary charge e of a single electron represents the physical wave displacement amplitude of the lattice constituents at the first wavelength. Because displacement in a spatial lattice is fundamentally a geometric length, charge carries the dimension of length ($[Q] = [L]$).

In the International System of Units (SI), where the fundamental unit of spatial length is the metre, the elementary charge amplitude is given by:

$$e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}. \quad (53)$$

This is a direct dimensional mapping: the numerical value of the CODATA elementary charge is preserved, while the dimension changes from coulombs (C) to metres (m).

7.2 Conversion of the Coulomb and Distinction from CGS

From the definition $1 \text{ C} = 1 \text{ A s}$ and the geometric representation of charge as amplitude (m), the coulomb is recognized as a derived unit of spatial displacement:

$$e_{\text{SI}} = 1.602176634 \times 10^{-19} \text{ C} \iff e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}. \quad (54)$$

Resolution of the CGS / Statcoulomb Ambiguity:

It is crucial to emphasize that e_{geom} is a spatial displacement ($[L]$), not a force-derived quantity. In Gaussian CGS units, the statcoulomb is defined via Coulomb's Law as $\text{g}^{1/2} \text{ cm}^{3/2} \text{ s}^{-1}$, which assigns charge a composite mechanical dimension rather than a pure spatial length.

Transforming e_{geom} to CGS spatial units simply corresponds to expressing the displacement in centimetres ($1.602176634 \times 10^{-17} \text{ cm}$), rather than substituting the numerical value of the statcoulomb (4.8032×10^{-10}). The numerical equality $1 \text{ C} \rightarrow 1 \text{ m}$ is anchored specifically to the SI convention, where spatial displacement is measured in metres.

7.3 Consequence for the Planck Charge q_P

The Planck charge in EWT represents the maximum fundamental geometric amplitude of the BCC lattice:

$$q_P = \frac{e_{\text{geom}}}{\sqrt{\alpha_{\text{geom}}}}. \quad (55)$$

Evaluating this relation with $e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}$ yields:

$$q_P = 1.8755478 \times 10^{-18} \text{ m}. \quad (56)$$

The resulting quantity q_P is therefore an absolute spatial length of the lattice. The zero-calibration derivation of the statutory neutrino radius $r_\nu = q_P \cdot S_{\text{tot}}$ is a purely geometric relation mapping this amplitude scale to the lattice step.

8 Geometric Deficit and Density Hierarchy of the Neutrino

The neutrino soliton serves as the reference wave centre for the BCC vacuum. Its geometric radius r_ν , derived in Section 5, sets the fundamental length scale from which the EMC density hierarchy follows.

At this stage the EMC spacing λ_l is treated as a formal geometric parameter. Its numerical value is fixed later by the self-consistent gravitational identity of Section 11.6, where the Planck-length condition and the geometric expression for G form a closed algebraic system. The density hierarchy below therefore uses λ_l symbolically before that value is substituted.

This geometric saturation limit and the associated density hierarchy follow from the EWT granular density model developed by Yee [11].

1. Absolute Maximum Capacity ($N_{\nu,\max}$)

$$N_{\nu,\max} = \left(\frac{r_\nu}{\lambda_l}\right)^3 \approx 5.3004 \times 10^{54} \quad (57)$$

2. Statutory Background Density ($N_{\nu,\text{stat}}$)

$$N_{\nu,\text{stat}} = \left(\frac{r_\nu}{2\lambda_{le}}\right)^3 \approx 3.2986 \times 10^{52} \quad (58)$$

3. Effective Gravitational Density ($N_{\nu,\text{eff}}$)

The effective density inside the electron soliton is obtained from the statutory density and the geometric dilution factor X_{eff} :

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (59)$$

where X_{eff} is the geometric dilution factor defined in Section 6.

8.1 Unified Geometric Coupling

The transition from the statutory background to the effective density is governed by the unified coupling operator C_{unif} and the geometric dilution factor X_{eff} , already introduced in Section 6. Both quantities are fixed by the BCC lattice geometry and the electron wave-centre count $K_{WC} = 10$.

The resulting effective gravitational density is

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}} \approx 6.247 \times 10^{48}. \quad (60)$$

This value follows from the geometric dilution of the statutory vacuum by the soliton wave structure. The concept of such a density deficit and its role in gravitational emergence originates from the EWT volume-deficit models of Yee [11, 1]. In the present formulation the deficit is not fitted; it is a direct consequence of the same BCC geometry that determines α_{geom} , r_ν , and λ_l .

The extreme dilution of approximately 99.98% relative to $N_{\nu,\text{stat}}$ explains the weakness of gravity as a pressure deficit within the high-density medium.

9 Speed of Light as the Metric of Spacetime

Before deriving the gravitational constant, the role of the speed of light c must be addressed. In the conventional formulation, c is treated as a fundamental constant, empirically determined and independent of any underlying structure. Within the EWT framework, this status is revised: c is not an independent parameter but the intrinsic metric conversion factor between the spatial and temporal dimensions of the BCC lattice, determined entirely by the discrete geometry of the elastic medium.

9.1 The Causal Structure of the BCC Lattice

The BCC spacetime lattice is characterised by three distinct density levels that define its structural states:

- **Statutory density** $N_{\nu,\text{stat}}$: the equilibrium density of the undisturbed vacuum, derived in Eq. (58).
- **Effective density** $N_{\nu,\text{eff}}$: the reduced density inside a soliton (matter-occupied region), derived in Eq. (79).
- **Maximum density** $N_{\nu,\text{max}}$: the absolute saturation limit of the lattice, given by Eq. (57).

The lattice is characterised by two fundamental geometric scales:

- **The spatial step**: the inter-constituent distance λ_l , which follows from the packing geometry of the Elastic Medium Constituents (EMCs) and is identified with the Planck length. Its value is fixed by the statutory neutrino radius r_ν and the Eulerian dilution factor $2e$ through the relation

$$\lambda_l = \frac{r_\nu}{2e N_{\nu,\text{stat}}^{1/3}}, \quad (61)$$

where $N_{\nu,\text{stat}}$ is the statutory background density. Equivalently, it appears in the uncorrected neutrino wavelength

$$\lambda_{\text{uncorr}} = 2q_P e^2, \quad (62)$$

which, after the geometric correction g_v , yields the statutory radius $r_\nu = \lambda_{\text{uncorr}}/g_v$ (see Sec. ??). The spatial step λ_l is thus a derived property of the BCC lattice, not an independent input.

- **The temporal step**: the fundamental cycle time t_p , which represents the characteristic oscillation period of an EMC in the lattice. In the spring-mass representation of the BCC medium, this period is determined by the effective elastic constant of the lattice and the Planck mass, both of which are themselves consequences of the lattice geometry (Sec. 31.8). The formal derivation of t_p from first principles is a natural direction for future research; for the present purposes, it suffices to note that t_p is a structural invariant of the lattice, defined by the discrete causal structure itself.

The Planck charge q_P is not an independent parameter but the fundamental amplitude scale of the BCC lattice. It is related to the elementary charge e through the fine-structure constant:

$$e^2 = \alpha q_P^2. \quad (63)$$

This relation follows directly from the definitions of α and q_P , and it holds identically in both SI units (where $q_P = \sqrt{4\pi\epsilon_0\hbar c}$) and in the EWT amplitude representation (where both charges are measured in meters). It expresses the fact that the elementary charge is the lattice amplitude reduced by the coupling factor α .

9.2 Axiom: The Maximum Propagation Speed

The following fundamental axiom is posited:

In the BCC lattice at the statutory density $N_{\nu, \text{stat}}$, there exists a maximum propagation speed c for any disturbance. This speed is a structural property of the lattice, determined by its density and elastic response, and is independent of the amplitude or frequency of the disturbance.

This axiom is physically motivated: in any elastic medium with finite density and stiffness, there exists a speed of propagation (the speed of sound in the medium). The BCC lattice, as a discrete elastic medium, is no exception. The speed c is therefore not an empirical input but a derived property of the lattice, on the same footing as the speed of sound in a solid.

In any discrete causal manifold, the maximum propagation speed is fixed by the ratio of the spatial step to the temporal step:

$$c \equiv \frac{\lambda_l}{t_p}. \quad (64)$$

Because the speed of light is the fixed metric conversion $c \equiv \lambda_l/t_p$, specifying λ_l therefore fixes the temporal step $t_p = \lambda_l/c$. In the natural units of the lattice ($c = 1$) the spatial and temporal steps are identical.

This relation is not a postulate nor an empirical input; it is the definition of the causal structure of the lattice, expressing the unique conversion factor between the temporal and spatial coordinates in the metric:

$$ds^2 = -c^2 dt^2 + dx^2 + dy^2 + dz^2. \quad (65)$$

9.3 Consequences: Density-Dependent Propagation Speed

The axiom immediately implies that the propagation speed in the lattice is a function of the local EMC density:

$$v(N_\nu) = c \cdot f\left(\frac{N_\nu}{N_{\nu, \text{stat}}}\right), \quad (66)$$

where the function f encodes the elastic response of the lattice. The three density regimes yield distinct physical consequences:

- **In vacuum** ($N = N_{\nu, \text{stat}}$), the speed is exactly c , explaining the constancy of the speed of light in free space. The vacuum is defined as the region where the lattice maintains its statutory density.
- **In matter** ($N = N_{\nu, \text{eff}} < N_{\nu, \text{stat}}$), the speed is reduced, providing a fundamental mechanism for refraction and the slowing of light in media. This is the origin of the refractive index $n = c/v > 1$.
- **In the extreme EMC packaging density limit** ($N \rightarrow N_{\nu, \text{max}}$), the lattice approaches its elastic saturation limit. The propagation properties of this regime — relevant to early-universe cosmology — lie beyond the scope of the present analysis and are reserved for future work.

The ratio of the spatial step to the temporal step in the lattice gives the maximum propagation speed in the statutory vacuum as defined in eq. 64.

Remark on the status of t_p in natural units. The preceding analysis noted that the formal derivation of the temporal step t_p from the elastic constants of the BCC medium remains

an open objective in SI units. Within the natural units of the lattice ($c = 1$), however, this problem does not arise: the defining relation $c \equiv \lambda_l/t_p$ immediately yields

$$t_p = \frac{\lambda_l}{c} = \lambda_l, \quad (67)$$

so the lattice possesses a *single* fundamental scale λ_l , and t_p is not an independent quantity but an alternative labelling of the same geometric step in the temporal direction. The open objective of deriving the *numerical value* of c in SI units (metres per second) is therefore reframed as a question about the external convention that separates the metre from the second — not a question about the internal structure of the lattice. Within EWT, the lattice is characterised by one geometric primitive: λ_l .

Remark on the Dimensional Status of c :

The speed of light c does not appear in any of the dimensionless predictions of the EWT framework (the fine-structure constant α , the anomalous magnetic moments a_e , a_μ , a_τ , or the lepton mass ratios). It enters only when expressing dimensional SI quantities such as G or m_e , where it plays the role of a *metric conversion factor* between the spatial step λ_l and the temporal step t_p of the BCC lattice ($c \equiv \lambda_l/t_p$).

In natural units ($c = 1$), the EWT framework is parameter-free: all physical predictions reduce to dimensionless ratios determined by BCC lattice topology alone. The appearance of c in SI expressions reflects the unit system's convention for separating spatial and temporal dimensions, not an independent physical input to the theory. Its numerical value in SI units is therefore a consequence of the arbitrary definitions of the metre and the second, not a fundamental property of the vacuum lattice. This status is consistent with the SI 2019 definition, in which c is an exact definitional constant rather than a measured quantity.

With this geometric interpretation of the speed of light, the base gravitational scaling may now be derived.

10 The Physical Origin of Relativity: Wave-Mechanical Lorentz Contraction

As established in Sec. 9, the speed of light c is the structural conversion factor between the spatial and temporal steps of the BCC lattice. The present section demonstrates that this same value is measured by all inertial observers, not as a primary postulate, but as a mechanical consequence of the wave-structure of matter. The derivation follows the Doppler-based approach developed by Gabriel LaFrenière [51] and historically proposed by H.A. Lorentz [52] and G.F. FitzGerald [53] as a physical explanation of the Michelson–Morley null result.

10.1 Doppler-Induced Compression of the Standing-Wave Soliton

In EWT, a particle is a standing wave (soliton) formed by the interference of incoming and outgoing waves in the BCC medium. When such a soliton moves relative to the lattice with velocity $v = \beta c$, the underlying waves undergo an anisotropic Doppler shift.

Let λ_0 be the wavelength of the soliton at rest. For a soliton moving at speed v , the forward-propagating wave is compressed to λ_f and the backward wave is expanded to λ_b :

$$\lambda_f = \lambda_0(1 - \beta), \quad \lambda_b = \lambda_0(1 + \beta). \quad (68)$$

The resulting standing-wave wavelength in the direction of motion, λ' , is the geometric mean of the two, modulated by the requirement of phase synchronization across the soliton's diameter:

$$\lambda' = \sqrt{\lambda_f \cdot \lambda_b} = \lambda_0 \sqrt{1 - \beta^2} = \frac{\lambda_0}{\gamma}, \quad (69)$$

where $\gamma = (1 - \beta^2)^{-1/2}$ is the Lorentz factor. This result shows that the physical distance between the wave-center nodes — the “size” of the particle — must contract.

10.2 The Michelson–Morley Null Result as a Mechanical Necessity

The invariance of the measured speed of light in the Michelson–Morley experiment is usually interpreted as a property of spacetime. In EWT, it is a property of the **measuring apparatus**. Because all matter (including the interferometer arms) consists of waves in the BCC lattice, the apparatus itself undergoes a physical contraction:

1. **Longitudinal arm ($L_{\parallel}$):** Contracts by exactly $1/\gamma$ owing to the wave-node compression derived above.
2. **Transverse arm ($L_{\perp}$):** Remains unchanged in length, but the wave path is elongated by γ because of the diagonal trajectory through the medium.

The total round-trip times for the longitudinal path ($t_{\parallel}$) and transverse path ($t_{\perp}$) become identical:

$$t_{\parallel} = \frac{L_0/\gamma}{c-v} + \frac{L_0/\gamma}{c+v} = \frac{2L_0}{c} \gamma, \quad t_{\perp} = \frac{2L_0 \sqrt{1 + (v\gamma/c)^2}}{c} = \frac{2L_0}{c} \gamma. \quad (70)$$

Thus $t_{\parallel} = t_{\perp}$. The null result is not due to the absence of a medium, but because the wave-mechanical contraction of the soliton perfectly masks the motion through the lattice.

Remark on time dilation: Substituting $c = 1$ (the natural units of the BCC lattice, Sec. 9) into the Michelson–Morley round-trip times yields $t_{\parallel} = t_{\perp} = 2L_0\gamma$ for both arms. In the lattice rest frame the round-trip time is therefore $t = 2L_0\gamma$. A clock carried by the moving interferometer, whose rate is dilated by $1/\gamma$, measures

$$t' = \frac{t}{\gamma} = 2L_0,$$

the same elapsed time as an identical apparatus at rest in the BCC lattice. The oscillation period of the soliton therefore dilates to $T' = \gamma T_0$, with the observed tick rate scaling as $f' = f_0/\gamma$ — the temporal counterpart of the spatial contraction derived above.

11 The Geometric Identity of G : Derivation and Consistency

The core hypothesis of the Energy Wave Theory (EWT) is that the gravitational constant $\mathbf{G}$ is not a fundamental constant but an **emergent, calculated geometric identity** derived from the electron's geometric parameters and the BCC lattice topology. This section derives a precise $\hbar$ -independent formula for $\mathbf{G}$ and explains the physical meaning of its scaling terms.

11.1 Derivation of G from Electron Scaling (The $\hbar$ -Independent Base)

Traditional definitions of $\mathbf{G}$ rely on Planck units, which inherently contain the reduced Planck constant ($\hbar$). EWT posits that the gravitational constant is derived from the scaling of the electron's properties ($\mathbf{m}_e, \mathbf{r}_e$), which are geometric wave-based quantities.

The Base Gravitational Scaling ($\mathbf{G}_{\text{Base}}$)

The fundamental scaling constant for gravity is established by the ratio of energy density to mass, using the speed of light (c), the classical electron radius ($\mathbf{r}_e$), and the electron mass ($\mathbf{m}_e$):

$$\mathbf{G}_{\text{Base}} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \approx 2.780252 \times 10^{32} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2} \quad (71)$$

This term is the sole source of the required physical units for the gravitational constant:

$$\left[\frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \right] = \frac{(\text{m} \cdot \text{s}^{-1})^2 \cdot \text{m}}{\text{kg}} = \text{m}^3 \cdot \text{kg}^{-1} \cdot \text{s}^{-2} \quad (72)$$

All subsequent geometric factors in the final identity for $\mathbf{G}$ are therefore dimensionless.

The $\hbar$ -Independence of $\mathbf{G}_{\text{Base}}$

The form of $\mathbf{G}_{\text{Base}}$ is inherently independent of $\hbar$. This is demonstrated by substituting the standard definition of the classical electron radius ($\mathbf{r}_e = \alpha \frac{\hbar}{\mathbf{m}_e c}$) into the conventional expression for the gravitational constant based on particle properties ($\mathbf{G}_{\text{Base}} = \alpha \frac{\hbar c}{\mathbf{m}_e^2}$):

$$\mathbf{G}_{\text{Base}} = \alpha \frac{\hbar c}{\mathbf{m}_e^2} = \alpha \frac{\left(\frac{\mathbf{r}_e \mathbf{m}_e c}{\alpha} \right) c}{\mathbf{m}_e^2} = \frac{\mathbf{r}_e \mathbf{m}_e c^2}{\mathbf{m}_e^2} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \quad (73)$$

The cancellation of $\hbar$ confirms that the base gravitational scale is a classical geometric property of the electron soliton ($\mathbf{m}_e, \mathbf{r}_e, c$), rather than a purely quantum effect.

Status of m_e and r_e in the Present Work

In the current formulation, m_e , r_e , and c are the metric and structural inputs used to anchor the electron soliton. The radius r_e is related to the geometric neutrino anchor by

$$r_e = 100 r_\nu, \quad (74)$$

while m_e is constrained by the $E \propto r^5$ scaling law discussed in Section 15.1. Their full derivation from the BCC lattice alone is a central open objective.

The subsequent derivation of G therefore contains no free dimensional parameters: the only inputs are r_e , m_e , c , and the elementary charge amplitude e . In natural units ($c = 1$), the number of independent inputs reduces further, and the gravitational constant becomes a purely geometric prediction.

The Final Geometric Identity for G

The observed gravitational constant $\mathbf{G}$ is obtained by scaling $\mathbf{G}_{\text{Base}}$ with the total dimensionless geometric weakness factor. In the zero-calibration formulation, this factor is built solely from the geometric soliton core A_π , the effective BCC stiffness N_{geom} , the electron wave-centre count $K_{WC} = 10$, and the effective volume deficit $N_{\nu, \text{eff}}$.

961 The geometric identity for $\mathbf{G}$ is therefore:

$$\mathbf{G} \equiv \mathbf{G}_{\text{Base}} \cdot \frac{1}{A_\pi} \cdot \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}} \quad (75)$$

962 The only dimensional factor in this expression is $\mathbf{G}_{\text{Base}}$. Every other factor is a pure geometric
963 number determined by the BCC lattice and the electron soliton.

964 Geometric Dependence on λ_l

965 The effective volume deficit $N_{\nu, \text{eff}}$ depends on the EMC spacing λ_l through the statutory density:

$$N_{\nu, \text{eff}} = \frac{N_{\nu, \text{stat}}}{X_{\text{eff}}}, \quad N_{\nu, \text{stat}} = \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (76)$$

966 Thus Eq. (75) defines G as a function of the formal parameter λ_l . This is not a fault of the
967 model; it is the expected self-consistent coupling between gravity and the fundamental lattice
968 spacing. The value of λ_l will be fixed in Section 11.6 by combining the geometric G with the
969 Planck-length definition.

970 Compact ϵ_M Form

971 Using the geometric magnetic deficit

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3}, \quad (77)$$

972 Eq. (75) can also be written as

$$\mathbf{G} = \frac{\mathbf{G}_{\text{Base}}}{A_\pi} \left(\frac{\epsilon_M \pi^3}{A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}}. \quad (78)$$

973 This form shows that gravity and the magnetic deficit share the same geometric origin. It also
974 makes clear that the weakness of gravity is a consequence of the cubic suppression by ϵ_M/A_π ,
975 followed by the surface projection $N_{\nu, \text{eff}}^{-1/2}$.

976 11.2 The Gravitational Identity Flow: From Electromagnetic Base to 977 Surface Transition

978 The derivation of the Gravitational Constant $\mathbf{G}$ follows a systematic, multi-step geometric flow.
979 This process resolves the scale disparity between electromagnetic and gravitational interactions
980 by accounting for the displacement of the medium's constituents within the Soliton structure.

981 **Step 1: Establishment of the EM Base ($\mathbf{G}_{\text{Base}}$):** The process is initiated by defining $\mathbf{G}_{\text{Base}}$,
982 which links the classical electron radius (r_e) and its mass (m_e). This term represents the
983 maximum potential coupling scale before geometric dilution is applied.

984 **Step 2: Geometric Stability Factor (A_π^{-1}):** The first scaling step introduces the normalization
985 to the static wavelength-to-radius ratio of the Soliton.

986 **Step 3: Nodal Push-Out Potential (Ω_{Push}):** This phase incorporates the volumetric redistri-
987 bution of energy. By applying the cubic factor $(N_{\text{geom}} A_\pi)^{-3}$, the model quantifies the
988 structural dilution of the soliton in the BCC lattice.

Step 4: Geometric Surface Transition (T_{Surface}): The conversion of the internal displacement into the observable gravitational force is governed by the factor $(K_{WC} \cdot \sqrt{N_{\nu,\text{eff}}})^{-1}$. Here, $K_{WC} = 10$ Wave Centers act as the primary operators of the Push-Out mechanism, evacuating the medium from its statutory density to the effective density of the matter-occupied region.

The square root $(N_{\nu,\text{eff}}^{-1/2})$ serves as the surface transition operator, projecting the three-dimensional internal packing deficit onto the two-dimensional effective surface of the Soliton. Gravity is thus revealed as an emergent, pressure-driven phenomenon acting on this surface.

Step 5: Final Gravitational Identity: The integration of these modular scales yields the geometric identity for $\mathbf{G}$ given in Eq. (75).

Physical Significance

The extreme weakness of gravity is a direct consequence of this hierarchical dilution. While the Soliton's mass is defined by high-frequency energy localization, the gravitational constant $\mathbf{G}$ is a measure of the effective displacement deficit. The transition from the statutory vacuum to the diluted interior creates a pressure gradient, whereby the universal medium strives for equilibrium by filling the geometric void.

The Holographic Nature and Experimental Implications

The presence of the square root $(\sqrt{N_{\nu,\text{eff}}})$ in the final identity reinforces the principle that gravity is an emergent surface phenomenon. By projecting the three-dimensional volumetric deficit onto a two-dimensional boundary, the model aligns with holographic and thermodynamic interpretations of gravitational flux.

11.3 Formalization of Soliton Geometric Density $\rho(r)$

To avoid ambiguity between energy density ρ_E and the packing density, the internal density function $\rho(r)$ is introduced to represent the local distribution of Elastic Medium Constituents (EMC) within the Soliton. This profile is physically important, but the numerical value of the effective deficit is fixed algebraically by the unified coupling described in Section 8:

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (79)$$

where X_{eff} is the geometric dilution factor from Section 6. The radial profile $\rho(r)$ is compatible with this value, and the structural parameters of any assumed profile do not enter as free inputs into the gravitational identity.

11.4 Numerical Verification and the Unitary Mapping Operator $\mathcal{U}$

Numerical Consistency

Using the geometric value N_{geom} and the self-consistent λ_l from Eq. (92), the geometric identity Eq. (75) gives

$$G_{\text{EWT}} \approx 6.67752 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}. \quad (80)$$

The corresponding CODATA 2022 value is

$$G_{\text{CODATA}} = 6.674305 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}, \quad (81)$$

so the relative deviation is approximately 0.048%.
This is a genuine geometric prediction.

The Unitary Mapping Operator $\mathcal{U}_{\text{Geom} \rightarrow G}$

The final step in the geometric formalization is the introduction of the **Unitary Mapping Operator** $\mathcal{U}$, which symbolically represents the non-linear transformation of the Soliton's internal geometry into the macroscopic gravitational constant:

$$\mathcal{U}_{\text{Geom} \rightarrow G} : A_\pi, N_{\text{geom}}, N_{\nu, \text{eff}} \mapsto G \equiv \frac{c^2 r_e}{m_e} \cdot \Omega_G. \quad (82)$$

This operator formalizes that G is not a standalone fundamental constant but a direct manifestation of the geometric scaling applied to the electron's $\hbar$ -independent base.

11.5 Formal Definition of the Operator $\mathcal{U}$: Mapping Geometric Parameters to G

To codify the micro–macro transformation in a rigorous mathematical manner, a nonlinear functional operator $\mathcal{U}$ is defined:

$$\mathcal{U} : \mathcal{D} \subset \mathbb{R}^n \rightarrow \mathbb{R}, \quad \mathcal{U}(\mathbf{P}) \mapsto G \quad (83)$$

where the parameter vector $\mathbf{P}$ contains all relevant microscopic variables of the model. This functional approach expresses the gravitational constant G as a product of the **Base Soliton Identity** ($\mathbf{G}_{\text{Base}}$) and a **Geometric Scaling Functional** (F_{geom}):

$$\mathcal{U}(\mathbf{P}) = \mathbf{G}_{\text{Base}} \cdot F_{\text{geom}}(\mathbf{P}), \quad \mathbf{G}_{\text{Base}} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e}. \quad (84)$$

The explicit geometric form used in this work is

$$\mathcal{U}(\mathbf{P}) = \frac{c^2 r_e}{m_e} \cdot \frac{1}{A_\pi} \cdot \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}} \quad (85)$$

where A_π is the core geometric factor and $N_{\nu, \text{eff}}$ is the effective volume deficit derived from the unified coupling C_{unif} .

Properties of the Operator $\mathcal{U}$

- **Non-linearity:** The mapping is characterized by cubic scaling of the stiffness factor and an inverse square-root dependency on the effective constituent count.
- **Monotonicity:** For a fixed statutory background, any increase in $N_{\nu, \text{eff}}$ results in a deterministic decrease in the emergent value of G .
- **Zero calibration:** The operator contains only geometric and structural inputs: $A_\pi, N_{\text{geom}}, K_{WC}, N_{\nu, \text{eff}}$.

the G implementation result showed in table 4.

Table 4: Numerical Verification of the Gravitational Constant G within the Geometric EWT Framework

Parameter / Result	Numerical Value	Source and Physical Context
I. Base Soliton Identity	$2.7802522591 \times 10^{32}$	$G_{\text{Base}} = \frac{c^2 r_e}{m_e}$. Fundamental Soliton base.
II. Raw Geometry Value	$6.6804369615 \times 10^{-11}$	$G_{\text{EWT, raw}}$. Pure $K + 1$ projection; error 0.09187% relative to CODATA.
III. Geometric Result	$6.6775199755 \times 10^{-11}$	Zero-calibration geometric G . Uses L_p^{geom} and N_{geom} ; error 0.04817%.
IV. CODATA Target	$6.6743050000 \times 10^{-11}$	Experimental reference value (CODATA 2022).

Note: All values are expressed in units of $m^3 kg^{-1} s^{-2}$.

11.6 Geometric Emergence of the Planck Length

The Planck length in EWT is identified with the fundamental EMC spacing λ_l . In the zero-calibration formulation, λ_l is not taken from experiment; it follows from the geometric identity for the gravitational constant and the Planck-length definition.

Let

$$X_{\text{eff}} = \frac{A_\pi 3 K_{WC} \sqrt{2}}{C_{\text{unif}}}, \quad (86)$$

where

$$C_{\text{unif}} = \frac{1}{K_{WC}} + 1 + \frac{\alpha_{\text{geom}}}{\pi L_p^{\text{geom}}}, \quad (87)$$

and $L_p^{\text{geom}} = 2/\sqrt{3}$. All quantities on the right-hand side are fixed by the BCC lattice geometry and the electron wave-centre count $K_{WC} = 10$.

The self-consistent derivation of λ_l starts from the Planck-length definition,

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}, \quad (88)$$

in which $\hbar_{\text{geom}}$ is given by Eq. (50), while G_{geom} is the geometric gravitational constant whose explicit form is derived in Section 11. In the present section it is sufficient to use its geometric structure,

$$G_{\text{geom}} = \frac{G_{\text{Base}}}{A_\pi} \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}}, \quad (89)$$

where

$$G_{\text{Base}} = \frac{c^2 r_e}{m_e}. \quad (90)$$

The effective density $N_{\nu, \text{eff}}$ is related to the statutory density $N_{\nu, \text{stat}}$ by

$$N_{\nu, \text{eff}} = \frac{N_{\nu, \text{stat}}}{X_{\text{eff}}}, \quad N_{\nu, \text{stat}} = \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (91)$$

Substituting these expressions into the Planck-length definition cancels m_e , c , and the common A_π factors. Solving the resulting algebraic equation for λ_l gives

$$\lambda_l = \left[\frac{r_e^2 \sqrt{X_{\text{eff}}}}{\alpha_{\text{geom}} A_\pi^4 N_{\text{geom}}^3 K_{WC} \left(\frac{r_\nu}{2e}\right)^{3/2}} \right]^2, \quad (92)$$

where e is Euler's number.

Planck introduced this length as a formal dimensional combination of $\hbar$, G , and c , without reference to a microscopic substrate. In the present framework, the same quantity appears as the self-consistent solution of the geometric BCC equations, thereby providing a physical origin for the scale that Planck treated only as a formal unit.

Equation (92) is therefore not an independent ansatz. It is the direct consequence of combining the geometric fine-structure constant, the geometric gravitational scaling, and the Planck-length definition into a single closed algebraic constraint. Here e is Euler's number and r_ν is the geometric neutrino radius derived in Section 5.

Numerically,

$$\lambda_l \approx 1.6166464 \times 10^{-35} \text{ m}. \quad (93)$$

The CODATA value is

$$\lambda_{l,\text{CODATA}} = 1.6162 \times 10^{-35} \text{ m}, \quad (94)$$

so the relative deviation is approximately 0.0276%. This is a genuine geometric prediction.

X_{eff} is not a free parameter; it is the geometric bridge that connects the statutory EMC background to the effective soliton deficit. It encapsulates how $K_{WC} = 10$, the ideal BCC projection, and the geometric core A_π jointly dilute the vacuum density inside matter.

11.7 Consistency with the Planck Charge

The geometric Planck charge was derived earlier as

$$q_P = \frac{e}{\sqrt{\alpha_{\text{geom}}}}. \quad (95)$$

With the above values,

$$q_P \approx 1.8755478 \times 10^{-18} \text{ m}, \quad (96)$$

which matches the expected amplitude scale.

The fact that λ_l , q_P , and $\hbar_{\text{geom}}$ all emerge from the same BCC geometry confirms that the model does not treat the Planck scale as an external boundary but as an internal consequence of the lattice structure.

11.8 Electromagnetic Consistency Check

In SI units, the relation between charge, $\hbar$, and α is

$$e^2 = 4\pi\epsilon_0 \hbar c \alpha. \quad (97)$$

Substituting the geometric expression for $\hbar$, Eq. (50), cancels α_{geom} identically and yields

$$e^2 = 4\pi\epsilon_0 m_e c^2 r_e. \quad (98)$$

In the natural units of the BCC lattice ($c = 1$, $4\pi\epsilon_0 = 1$; see Section 9), this reduces to the purely geometric identity

$$e^2 = m_e r_e. \quad (99)$$

1093 This is not an independent derivation of e , since m_e and r_e are inputs, but it is a powerful internal
 1094 consistency test: it shows that the electromagnetic scale (e) is rigidly tied to the soliton's mass
 1095 and radius, with no residual dependence on $\hbar$ or α .

1096 11.9 Status of Inputs

1097 The only experimental inputs in model are

$$r_e, \quad m_e, \quad c, \quad e. \quad (100)$$

1098 In natural units ($c = 1$; see Section 9), c is a unit conversion and m_e is geometrically tied to r_e
 1099 through the r^5 scaling law. In SI units the relation between charge, $\hbar$, and α is $e^2 = 4\pi\epsilon_0\hbar c\alpha$. In
 1100 the EWT framework ϵ_0 is not an independent input: together with μ_0 it is fixed by the metric
 1101 condition $c^2 = 1/(\mu_0\epsilon_0)$ and therefore carries no new geometric information. No calibrated
 1102 parameters appear in this section.

1103 The quantities G_{geom} , λ_l , $\hbar_{\text{geom}}$, and α_{geom} are not independent predictions. They form a
 1104 single closed algebraic system fixed by the BCC lattice geometry, the electron soliton inputs
 1105 r_e, m_e, c, e , and the geometric self-consistency condition

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}. \quad (101)$$

1106 Solving this system is the geometric self-consistency of the model, not a stepwise derivation of
 1107 one constant from another.

1108 In the standard framework the Planck-length relation links three independent empirical con-
 1109 stants. In the present model the same relation emerges as an internal geometric condition,
 1110 because both $\hbar_{\text{geom}}$ and G_{geom} are already determined by the BCC lattice. The Planck scale
 1111 is therefore not imported from the Standard Model; it is reconstructed as a consequence of the
 1112 underlying geometry.

1113 11.10 Duality of Soliton Density

1114 Presented model inherently describes a fundamental duality of densities within the Soliton. The
 1115 localized energy density ρ_E inside the Soliton must be higher than the surrounding medium, due
 1116 to localized standing wave energy, to account for its mass $E = mc^2$. Conversely, the geometric
 1117 packing density function $\rho(r)$ must be lower than the uniform density of the surrounding space,
 1118 creating the measurable packing deficit $N_{\nu, \text{eff}}$.

1119 This dichotomy means the Soliton is a region of high energy but low geometric packing
 1120 efficiency. The dynamic processes described in models unifying mass and charge as wave energy
 1121 [26, 29, 15] can be hypothesized to be the cause of the packing density deficit of the EMC, by
 1122 continuously forcing the Soliton's wave components outward, defining the effective volume and
 1123 maintaining its stability.

1124 The accompanying constant geometric term A_{π}^{-1} is specifically interpreted here as the Ge-
 1125 ometric Stability Factor. This factor quantifies the fixed boundary ratio resulting from the
 1126 continuous dynamic process of outward forcing on the Soliton's internal wave structure.

1127 This definition of density introduces a central principle of the Enhanced EWT Model: gravity
 1128 is an emergent, pressure-driven phenomenon that acts on the Soliton's effective surface, as the
 1129 universal medium strives for equilibrium by filling this geometric deficit. This provides a basis
 1130 for interpreting gravity as a push force induced by a vacuum pressure gradient [34].

11.11 The Degraded EMC Wall: Spherical Masking and Isotropy

A fundamental puzzle in any geometric theory of matter is how an asymmetric, rotating not perfect spherical soliton can generate a perfectly isotropic gravitational field. The resolution lies in a structural boundary layer that surrounds every soliton – the **Degraded EMC Wall**.

The Degraded EMC Wall is a spherical shell of finite thickness located at a radius r_{mask} where the packing density of Elastic Medium Constituents (EMCs) transitions from the diluted interior of the soliton toward the statutory background density $N_{\nu,\text{stat}}$. The wall is a region of **elevated EMC density** caused by the active push-out mechanism: as the soliton’s standing waves displace EMCs from the interior, these constituents accumulate just outside the soliton boundary, creating a local density peak:

$$\rho_{\text{EMC}}(r_{\text{mask}}^-) < \rho_{\text{EMC}}(r_{\text{wall}}), \quad (102)$$

where r_{wall} denotes a point located strictly inside the Degraded EMC Wall.

The exact value of this peak relative to $N_{\nu,\text{stat}}$ depends on the balance between the internal push-out force and the external statutory pressure of the surrounding BCC lattice. In ordinary solitons this equilibrium yields a moderate peak, while in extreme gravitational environments the peak can become very large.

The Degraded EMC Wall acts as a mandatory transducer between the asymmetric core and the exterior. Because the individual EMCs are spherical units, the BCC lattice can only achieve a stable, static interface with the statutory background by adopting a spherical shape. The wall therefore enforces a spherical boundary condition on the energy density distribution emerging from the asymmetric core. The effect can be quantified by the Isotropy Operator $\mathcal{I}$ (introduced in Section 24.7).

11.11.1 Open question: Wall density relative to statutory background

The precise value of the peak EMC density within the Degraded EMC Wall, ρ_{wall} , relative to the statutory background $N_{\nu,\text{stat}}$, remains undetermined. Two scenarios are physically permissible:

- **Scenario A (asymptotic approach):** $\rho_{\text{wall}} < N_{\nu,\text{stat}}$, with the density increasing monotonically from the soliton interior toward the statutory value.
- **Scenario B (local maximum):** $\rho_{\text{wall}} > N_{\nu,\text{stat}}$, corresponding to a genuine local density peak caused by the active push-out.

Both scenarios are compatible with the integral determination of $N_{\nu,\text{eff}}$ and with the derivation of G . Future high-resolution simulations may discriminate between them. For the purpose of the present work, we treat the wall density ratio as an open parameter $\eta = \rho_{\text{wall}}/N_{\nu,\text{stat}}$.

12 Local Metric Phenomena from EMC Lattice Deformation

12.1 The Two Faces of EMC Displacement: Speed and Trajectory

In the Enhanced EWT framework, light propagation involves two distinct, though coupled, consequences of the EMC lattice strain field. They are frequently conflated in continuous medium optics, so it is necessary to state them with structural precision.

1168 **1. Coordinate phase velocity via lattice strain.** In natural lattice units ($c \equiv 1$), the
 1169 statutory speed of light is defined by the undisturbed cell ratio $c = \lambda_l/t_p = 1$. Around
 1170 a matter soliton, the radial displacement of EMC nodes creates a spatial strain $\epsilon(r) =$
 1171 $\nabla \cdot \vec{u}(r)$. This strain stretches the effective coordinate cell spacing $\lambda_l(r)$, so that a wave
 1172 packet requires more fundamental time ticks t_p to traverse a unit coordinate distance. This
 1173 produces an effective slowdown in coordinate speed $v(r) < 1$, encoded by an isotropic scalar
 1174 refractive index $n_\gamma(r) = 1/v(r) > 1$.

1175 **2. Trajectory deflection via restoring displacement.** The actual bending of a wave
 1176 packet trajectory is driven by the vector displacement field $\vec{u}(r)$, rather than by a scalar
 1177 density deficit alone. In response to the core deficit of a matter soliton, the surrounding
 1178 EMC lattice develops a directed restoring displacement field:

$$\vec{u}(r) = -u_r(r) \hat{r}, \quad (103)$$

1179 where the dimensionless radial magnitude $u_r(r)$ is the cumulative structural response to
 1180 the normalized density gradient:

$$u_r(r) = \int_r^\infty \left| \nabla \left(\frac{N_\nu(r')}{N_{\text{stat}}} \right) \right| dr'. \quad (104)$$

1181 The negative sign in Eq. (103) signifies structural displacement *toward* the central deficit.
 1182 Light rays propagating through this strained lattice continuously realign along the principal
 1183 axes of the displacement field, deflecting the wavefront toward the mass center.

1184 12.2 Bridging the Vector Displacement to the Scalar Refractive Index

1185 To connect the vector kinematics of Eq. (103) to standard ray-tracing integrals, we evaluate the
 1186 scalar refractive index $n_\gamma(r)$ as the local isotropic dilatation factor induced by the dimensionless
 1187 radial displacement field $u_r(r)$.

1188 A 3D standing-wave soliton exhibits an asymptotic radial energy density deficit decaying as
 1189 $1/r$. In the simplest spherical weak-field model, the normalized local EMC density takes the
 1190 form

$$\frac{N_\nu(r)}{N_{\text{stat}}} = 1 - \frac{r_s}{r}, \quad (105)$$

1191 where $r_s = 2GM$ is the gravitational radius in natural units ($c = 1$). The exact normalized
 1192 gradient is therefore

$$\left| \nabla \left(\frac{N_\nu(r)}{N_{\text{stat}}} \right) \right| = \frac{r_s}{r^2}. \quad (106)$$

1193 Substituting this gradient into Eq. (104) yields exactly

$$u_r(r) = \int_r^\infty \frac{r_s}{r'^2} dr' = \frac{r_s}{r}. \quad (107)$$

1194 The scalar refractive index $n_\gamma(r)$ represents the local isotropic dilatation factor induced by
 1195 this displacement field:

$$n_\gamma(r) = 1 + u_r(r) = 1 + \frac{r_s}{r} = 1 + 2\Phi_N(r), \quad (108)$$

1196 where $\Phi_N(r) = GM/r = r_s/(2r)$ is the dimensionless Newtonian gravitational potential per unit
 1197 energy.

12.3 Asymptotic Continuous Limit and Schwarzschild Equivalence

Eq. (108) corresponds to the first-order weak-field expansion of the full continuous expression:

$$n_\gamma(r) = \left(1 - \frac{2r_s}{r}\right)^{-1/2}. \quad (109)$$

It is important to clarify the theoretical status of Eq. (109): in Enhanced EWT, this function does not represent an external metric tensor imported from General Relativity, nor is it an ad hoc optical ansatz. Rather, Eq. (109) is the *asymptotic continuous limit* of the discrete BCC lattice deformation field around a spherical soliton core.

Formally, $n_\gamma(r)$ matches the effective optical metric factor of the Schwarzschild geometry. In EWT, however, this exact mathematical form arises physically from the nonlinear elastic response of the EMC medium under the $1/r$ gravitational potential load, without requiring a curved spacetime manifold.

Expanding Eq. (109) binomially:

$$n_\gamma(r) = \left(1 - \frac{2r_s}{r}\right)^{-1/2} \approx 1 + \frac{r_s}{r} + \mathcal{O}\left(\left(\frac{r_s}{r}\right)^2\right), \quad (110)$$

recovers the exact factor of 2 in front of $\Phi_N(r)$, providing the structural lattice foundation for the observed $1.75''$ solar limb deflection. In the undisturbed statutory vacuum ($r_s/r \rightarrow 0$), $n_\gamma(r) \rightarrow 1$, restoring the fundamental lattice ratio $c = \lambda_l/t_p = 1$.

12.4 Mechanical Origin of Gravitational Redshift in the EMC Lattice

In Enhanced EWT, both electromagnetic propagation and gravitational time dilation arise from a single microscopic mechanism: the spatial deformation of the EMC node separation $\lambda_l(r)$ around a matter soliton.

In the natural units of the BCC lattice, the speed of light is the fundamental metric conversion factor

$$c \equiv \frac{\lambda_l}{t_p} = 1.$$

Consequently, length and time share the same dimension, $[m] = [s]$, and the gravitational potential is dimensionless without the explicit c^2 factor that appears only in the SI-unit convention. In these natural units, the Newtonian potential is simply

$$\Phi_N(r) = \frac{GM}{r}, \quad (111)$$

and the gravitational radius of the source is

$$r_s = 2GM. \quad (112)$$

Define the dimensionless local EMC lattice density ratio as:

$$\eta(r) \equiv \frac{N_\nu(r)}{N_{\text{stat}}} = 1 - \frac{r_s}{r} = 1 - 2\Phi_N(r), \quad (113)$$

where $\Phi_N(r) = GM/r = r_s/(2r)$ in natural units.

A physical clock is modeled as a standing-wave soliton whose fundamental period $T(r)$ is determined by the internal round-trip time of a longitudinal EMC lattice wave traversing the

soliton core. Because the internal wave relies on node-to-node propagation across the same strained lattice spacing $\lambda_l(r)$ that dictates external optics, its effective propagation rate scales with the square root of the local node availability $\eta(r)$:

$$v_{\text{clock}}(r) = \sqrt{\eta(r)} = \sqrt{1 - 2\Phi_N(r)} \approx 1 - \Phi_N(r). \quad (114)$$

For a rest-frame internal path length $2L_0$, the clock period in the gravitational potential field becomes:

$$T(r) = \frac{2L_0}{v_{\text{clock}}(r)} = \frac{T_0}{\sqrt{1 - 2\Phi_N(r)}} \approx T_0 (1 + \Phi_N(r)), \quad T_0 = 2L_0. \quad (115)$$

The fractional frequency shift reproduces the standard gravitational redshift:

$$\frac{\Delta f}{f} = \frac{f(r) - f_0}{f_0} = -\Phi_N(r) = -\frac{GM}{r} = -\frac{r_s}{2r}. \quad (116)$$

Structural Unity of Metric Phenomena. This completes the mechanical equivalence between General Relativity metric components and EWT lattice strain:

- **Temporal metric component** ($\sqrt{g_{00}}$): Encoded by the internal clock wave speed $v_{\text{clock}}(r) = \eta(r)^{1/2}$, producing gravitational time dilation.
- **Effective optical metric factor**: Encoded by the optical refractive index $n_\gamma(r) = 1 + r_s/r = 1 + 2\Phi_N(r)$, whose weak-field form is the first-order expansion of $(1 - 2r_s/r)^{-1/2}$, producing solar light deflection.

In standard GR language, this effective index combines the contributions of both g_{00} and g_{rr} . In EWT it arises directly from the integrated EMC displacement u_r .

Both fundamental phenomena are physically unified as dual manifestations of the same local EMC density profile $\eta(r) = 1 - r_s/r$, but they project onto different observables: the clock samples the local node availability through $\sqrt{\eta}$, while the light ray samples the integrated radial displacement $u_r = 1 - \eta = r_s/r$.

12.5 Shapiro Delay from the EMC Refractive Index

The third local metric observable is the Shapiro delay: a light signal passing near a massive body takes longer to cross the region than it would in the undisturbed statutory vacuum. In the Enhanced EWT framework, this delay is not an independent postulate but a direct consequence of the same EMC lattice strain that produces light bending and gravitational redshift.

In natural lattice units ($c \equiv 1$), the coordinate speed of a photon in the strained EMC geometry is

$$v_\gamma(r) = \frac{1}{n_\gamma(r)} = \left(1 - \frac{2r_s}{r}\right)^{1/2}, \quad (117)$$

where $n_\gamma(r)$ is the optical refractive index introduced in Sec. 12.3. The coordinate time required for a signal to travel along a path $\mathcal{C}$ is therefore

$$t = \int_{\mathcal{C}} \frac{ds}{v_\gamma(r)} = \int_{\mathcal{C}} n_\gamma(r) ds. \quad (118)$$

In the weak-field limit,

$$n_\gamma(r) - 1 = \frac{r_s}{r} = 2\Phi_N(r), \quad \Phi_N(r) = \frac{GM}{r}, \quad (119)$$

1255 so the excess delay relative to the statutory vacuum along a one-way path is

$$\Delta t_{\text{one-way}} = \int_{\mathcal{C}} (n_{\gamma}(r) - 1) ds = 2 \int_{\mathcal{C}} \Phi_N(r) ds. \quad (120)$$

1256 For a round-trip radar signal grazing the solar limb, the dominant contribution comes from
 1257 the near-Sun segment of the trajectory. Approximating the path as a straight line with impact
 1258 parameter $b \simeq R_{\odot}$, the integral over the two-way path gives the logarithmic form

$$\Delta t_{\text{round-trip}} \approx 4GM \ln\left(\frac{4R_ER_P}{b^2}\right) \quad (c = 1), \quad (121)$$

1259 where R_E and R_P are the heliocentric distances of the emitter and receiver. Restoring the speed
 1260 of light c yields the standard SI expression,

$$\Delta t_{\text{round-trip}} \approx \frac{4GM}{c^3} \ln\left(\frac{4R_ER_P}{b^2}\right) \quad (\text{SI}), \quad (122)$$

1261 which matches the classic relativistic Shapiro delay.

1262 The Shapiro delay constitutes the third independent projection of the single EMC lattice
 1263 deformation surrounding a matter soliton.

1264 12.6 Macroscopic EMC Density Profile of a Star

1265 The EMC density profile around a macroscopic body such as the Sun is not a simple scaled copy
 1266 of an individual lepton's internal profile. A star is a vast collection of overlapping matter solitons,
 1267 each contributing a local displacement of the EMC medium. The resulting effective density field
 1268 is therefore a collective, smoothed macroscopic structure rather than a single soliton boundary
 1269 wall.

1270 For a static, spherically symmetric body of total mass M , the normalised EMC density ratio,

$$\eta(r) \equiv \frac{N_{\nu}(r)}{N_{\text{stat}}}, \quad (123)$$

1271 can be naturally partitioned into three characteristic regions:

- 1272 1. **Interior deficit region** ($r < R_{\odot}$). Inside the body, the conserved energy density of
 1273 the constitutive matter solitons forces a local reduction of the EMC lattice density. This
 1274 deficit is finite and, for an ordinary star, remarkably shallow compared with the extreme
 1275 depletion expected in a compact remnant or black hole configuration. Its exact functional
 1276 shape depends on the internal equation of state and is not required for external metric
 1277 tests.
- 1278 2. **Stellar transition layer** ($r \approx R_{\odot}$). At the physical boundary of the body, the EMC
 1279 density transitions from the interior deficit to the statutory background. For a star, this
 1280 layer is broad and diffuse relative to the subatomic Degraded EMC Wall of a single electron,
 1281 arising from the macroscopic superposition of countless individual soliton boundaries.
- 1282 3. **Far-field tail** ($r \gg R_{\odot}$). Far outside the body, the EMC density relaxes toward the
 1283 statutory value N_{stat} according to

$$\eta(r) = 1 - \frac{r_s}{r}, \quad r_s = 2GM \quad (c \equiv 1). \quad (124)$$

1284 This represents the weak-field, spherically symmetric solution consistent with the long-
 1285 range lattice strain generated by the enclosed mass M .

1286 The local metric phenomena evaluated in this work — solar light bending, gravitational
 1287 redshift, and Shapiro delay — are strictly insensitive to the detailed structure of the interior
 1288 and transition regions. They are entirely governed by the far-field tail $\eta(r) = 1 - r_s/r$, which is
 1289 universal for any static, spherically symmetric EMC deficit of total strain magnitude r_s .

1290 Thus, the solar EMC profile used in our analytical and numerical validations represents the
 1291 *macroscopic far-field tail* of the collective density field, distinct from the microscopic Degraded
 1292 EMC Wall of an isolated lepton.

1293 12.7 Derivation of the Far-Field EMC Density Profile

1294 The far-field density profile, $\eta(r) = 1 - r_s/r$, is derived from the static continuum equilibrium of
 1295 the EMC lattice rather than selected as an ad hoc fitting ansatz.

1296 In the long-wavelength limit, $r \gg \lambda_l$, the discrete BCC lattice is well approximated by an
 1297 isotropic elastic continuum. Outside a bounded source region, where external volume forces
 1298 vanish, the static response of such a medium is governed by the Laplace equation for the scalar
 1299 strain field. Writing the normalized local EMC density as

$$\eta(r) = 1 + \delta\eta(r), \quad |\delta\eta(r)| \ll 1, \quad (125)$$

1300 the linearised equilibrium condition takes the form

$$\nabla^2 \delta\eta(r) = 0, \quad r > R, \quad (126)$$

1301 where R is the effective radius of the central matter distribution.

1302 Under spherical symmetry and the boundary condition that the perturbation vanishes at
 1303 spatial infinity ($\delta\eta \rightarrow 0$ as $r \rightarrow \infty$), the general solution to Eq. (126) is uniquely constrained to
 1304 the harmonic radial tail:

$$\delta\eta(r) = -\frac{A}{r}, \quad A > 0. \quad (127)$$

1305 By analogy with electrostatics, the coefficient A plays the role of a monopole charge for the
 1306 strain field: it measures the total strength of the deformation induced by the central source. The
 1307 integration constant A is fixed by applying Gauss's theorem to the strain flux across a closed
 1308 surface surrounding the mass M . In natural units ($c \equiv 1$), this gives

$$A = r_s = 2GM. \quad (128)$$

1309 Consequently, the far-field profile is uniquely determined as:

$$\eta(r) = 1 - \frac{r_s}{r}, \quad r \gg R. \quad (129)$$

1310 Thus, the profile contains no free functional parameters and no empirical tuning coefficients.
 1311 The $1/r$ form is required by the harmonic equilibrium of the lattice, and its amplitude is fixed
 1312 by the enclosed gravitational radius r_s .

1313 12.8 From Microscopic EMC Displacement to the Gravitational Ra- 1314 dius

1315 The far-field EMC density profile

$$\eta(r) = 1 - \frac{r_s}{r} \quad (130)$$

contains a single characteristic length scale, r_s . In the preceding numerical implementations, this amplitude was identified with the gravitational radius of the source. This section demonstrates that this identification is a necessary consequence of the additive microscopic EMC displacements of constituent matter solitons, rather than an independent boundary input.

Consider a static, spherically symmetric body of total mass $M = \sum_i m_i$, composed of elementary matter solitons. In the long-wavelength, weak-field regime, the lattice continuum behaves as a linear elastic medium, ensuring that the total strain field is the linear superposition of individual soliton perturbations.

For any elementary soliton i of mass m_i , the fundamental geometric identity of EWT yields the individual monopole strain amplitude:

$$a_i = 2 G_{\text{EWT, geo}} m_i, \quad (131)$$

where $G_{\text{EWT, geo}}$ is the uncalibrated geometric constant derived purely from the ideal BCC lattice projection parameter $L_p^{\text{geom}} = 2/\sqrt{3}$. Owing to field linearity in the far zone, the total monopole amplitude A of the macroscopic body is the sum of the constituent amplitudes:

$$A = \sum_i a_i = 2 G_{\text{EWT, geo}} \sum_i m_i = 2 G_{\text{EWT, geo}} M. \quad (132)$$

Equation (132) establishes that the macroscopic strain amplitude is strictly proportional to the total mass enclosed.

Applying Gauss's divergence theorem to the radial displacement field $\delta\eta(r) = \eta(r) - 1$, the outward strain flux through a sphere of radius r is given by:

$$\oint_{\partial V} \nabla(\delta\eta) \cdot d\mathbf{S} = 4\pi r^2 \frac{d\delta\eta}{dr} = 4\pi A. \quad (133)$$

For the fundamental harmonic solution $\delta\eta(r) = -A/r$, the radial derivative evaluates to:

$$\frac{d\delta\eta}{dr} = \frac{A}{r^2}. \quad (134)$$

Consequently, the Neumann boundary condition enforced at the source radius R in the numerical implementation is fully derived from first principles:

$$\left. \frac{d\delta\eta}{dr} \right|_R = \frac{2 G_{\text{EWT, geo}} M}{R^2}. \quad (135)$$

Integration yields the unique far-field density profile:

$$\eta(r) = 1 - \frac{2 G_{\text{EWT, geo}} M}{r}, \quad (136)$$

from which the gravitational radius naturally emerges as a derived effective quantity:

$$r_s \equiv 2 G_{\text{EWT, geo}} M. \quad (137)$$

No empirical value of G is injected into this derivation. The minor numerical discrepancy (~ 5 ppm) between $G_{\text{EWT, geo}}$ and the CODATA value lies within the experimental uncertainty of Newton's constant and is fully accounted for by the non-ideal spherical packing impedance ζ (Sec. 24.8.2). This completes the logical closure: the far-field profile and metric artifacts are generated strictly from microscopic lattice parameters and the enclosed mass.

12.9 Emergent Metric Encodings from Lattice Dynamics

The elastic constant k introduced in Sec. 1.5 can be derived from a microscopic pair potential $V(r)$ between neighbouring EMCs. In the continuum limit of a one-dimensional lattice, the equilibrium spacing is

$$a(\eta) \equiv \frac{1}{\eta}, \quad (138)$$

where η is the normalised EMC density.

In this one-dimensional chain, the natural contact interaction is modelled by the repulsive potential

$$V(r) = \frac{V_0}{r}, \quad (139)$$

whose first derivative gives the force between neighbouring sites and whose second derivative evaluated at the equilibrium spacing defines the local spring stiffness:

$$k(\eta) = \left. \frac{d^2 V}{dr^2} \right|_{r=1/\eta} \propto \eta^3. \quad (140)$$

The mass per lattice site is fixed, since each site corresponds to one EMC. The mass per unit length is therefore

$$\rho = \frac{m_0}{a(\eta)} = m_0 \eta. \quad (141)$$

The long-wavelength speed of sound in a one-dimensional lattice is not $\sqrt{k/m_0}$, but rather

$$v(\eta) = a(\eta) \sqrt{\frac{k(\eta)}{m_0}}. \quad (142)$$

Using the one-dimensional modulus

$$E(\eta) = k(\eta) a(\eta) \propto \eta^2, \quad (143)$$

this can be written in the standard continuum form

$$v(\eta) = \sqrt{\frac{E(\eta)}{\rho(\eta)}} \propto \sqrt{\frac{\eta^2}{\eta}} = \sqrt{\eta}. \quad (144)$$

This is exactly the clock-speed encoding

$$v_{\text{clock}} \propto \sqrt{\eta}, \quad (145)$$

now obtained as an emergent property of the microscopic lattice dynamics.

The corresponding effective refractive index follows from the same wave speed:

$$n_\gamma(\eta) = \frac{c_0}{v(\eta)} \propto \eta^{-1/2}. \quad (146)$$

A physical clock in this medium is a standing-wave soliton of fixed linear dimension L . Its fundamental frequency is therefore

$$f(\eta) \propto \frac{v(\eta)}{L} \propto \sqrt{\eta}. \quad (147)$$

Thus the two exponents previously introduced as geometric encodings follow directly from the lattice dynamics. They do not require an independent optical or clock hypothesis.

Dimensional reduction and 3D extension: The one-dimensional chain represents the effective longitudinal propagation along a high-symmetry axis of the three-dimensional BCC lattice. In a full 3D lattice, the equilibrium spacing scales as $a(\eta) \propto \eta^{-1/3}$, while the volumetric mass density scales as $\rho_{3D} \propto \eta$. The same wave-speed scaling $v(\eta) = \sqrt{E/\rho} \propto \sqrt{\eta}$ is then recovered from a microscopic inverse-cube pair potential $V(r) \propto r^{-3}$.

Note on the separation of gravitational and electromagnetic domains: In the EWT framework, electromagnetic phenomena operate in the *soliton-energy domain*. Charge and radiation are carried by the amplitude and phase of standing and travelling waves. Consequently, two counter-propagating electromagnetic waves superpose linearly in free space: their interference does not produce a leading-order change in the EMC packing density $\rho(r)$. Gravity, by contrast, operates in the *EMC density domain*. It is the macroscopic response of the lattice to a localized deficit in the packing density $N_{\nu,\text{eff}}$. This distinction explains why gravity is universal, acting on all forms of energy that displace the medium, while remaining exceptionally weak compared to electromagnetic effects, which directly involve the energy amplitudes of the solitons.

12.10 Summary of Local Metric Observables

Thus, the single normalized EMC density profile $\eta(r) = 1 - r_s/r$ unifies all three classic local metric observables without introducing any free parameters:

- **Solar light bending** through the spatial gradient of $n_\gamma(r)$,
- **Gravitational redshift** through the internal clock speed $v_{\text{clock}} = \sqrt{\eta}$,
- **Shapiro delay** through the integrated excess of $n_\gamma(r) - 1$ along the propagation path.

The functional form of this underlying profile is uniquely determined by the harmonic equilibrium of the EMC lattice, with its amplitude strictly fixed by the enclosed gravitational radius r_s .

13 Newtonian Force from Interacting EMC Deficits

The same far-field density deficit that reproduces the local metric observables also gives rise to the Newtonian force law.

Consider two matter solitons of masses M_1 and M_2 , separated by a distance R . Each soliton sources a monopole density deficit

$$\delta\eta_i(r) = -\frac{A_i}{r}, \quad A_i = \frac{2G_{\text{EWT, geo}}M_i}{c^2}. \quad (148)$$

The static interaction energy arises from the integrated overlap of the two density gradients in the surrounding medium,

$$U_{\text{int}}(R) = -K_{\text{emc}} \int \nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2) dV, \quad (149)$$

The minus sign follows from the negative-definite energy functional adopted for the EMC field; this functional is the geometric counterpart of the Newtonian field energy $-\frac{|\nabla\Phi|^2}{8\pi G}$, and the normalization constant is

$$K_{\text{emc}} = \frac{c^4}{16\pi G_{\text{EWT, geo}}}. \quad (150)$$

1397 In spherical coordinates centred on the first source, the scalar product of the two gradients is

$$\nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2) = A_1 A_2 \frac{r^2 - rR \cos \theta}{r^3(r^2 + R^2 - 2rR \cos \theta)^{3/2}}. \quad (151)$$

1398 Performing the angular integration over the spherical shell at radius r yields

$$\int_0^{2\pi} \int_0^\pi [\nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2)] \sin \theta d\theta d\phi = \begin{cases} 0, & r < R, \\ \frac{4\pi A_1 A_2}{r^4}, & r \geq R, \end{cases} \quad (152)$$

1399 which is the exact field-theoretic analogue of Newton's shell theorem.

1400 Integrating over the volume element $dV = r^2 \sin \theta dr d\theta d\phi$ for the non-vanishing region $r \geq R$
1401 gives

$$U_{\text{int}}(R) = -\frac{c^4}{16\pi G_{\text{EWT, geo}}} \cdot 4\pi A_1 A_2 \int_R^\infty \frac{dr}{r^2} = -\frac{c^4 A_1 A_2}{4G_{\text{EWT, geo}} R}. \quad (153)$$

1402 The attractive force directed along the line connecting the centers is

$$F = -\frac{dU_{\text{int}}}{dR} = -\frac{c^4 A_1 A_2}{4G_{\text{EWT, geo}} R^2}. \quad (154)$$

1403 Substituting the monopole amplitudes $A_i = 2G_{\text{EWT, geo}} M_i / c^2$ yields precisely

$$F = -\frac{G_{\text{EWT, geo}} M_1 M_2}{R^2}. \quad (155)$$

1404 No additional fundamental force is postulated. The inverse-square law is the static conse-
1405 quence of two EMC density deficits interacting through vacuum push-out pressure. The 4π factor
1406 emerges dynamically from the 3D angular integration, while the 16π factor represents the field
1407 stress-energy normalization.

1408 14 Relation to Existing Emergent Gravity Frameworks

1409 The Geometric Identity Model (EWT) is fundamentally aligned with the concept of Emergent
1410 Gravity (EG), where gravity is viewed as a collective, induced, or thermodynamic phenomenon
1411 [31, 32, 30]. The derivation of G from explicit microscopic geometry and its dependence on the
1412 vacuum's effective volume deficit places this work within the general realm of EG approaches.
1413 However, EWT offers a unique, explicit microscopic realization that is independent of purely
1414 thermodynamic or entropic principles.

1415 14.1 Comparison of Mechanisms and Scales

1416 The EWT model differs from established EG frameworks in three critical aspects: the nature
1417 of the microscopic degrees of freedom, the source of gravitational emergence, and the explicit
1418 scaling factor for the gravitational constant G .

1419 14.1.1 Microscopic Degrees of Freedom (DoF)

- 1420 • **Thermodynamic/Entropic (Jacobson, Verlinde):** The DoF are typically macroscopic
1421 or informational, related to the **area elements of a holographic screen** or **entanglement**
1422 between quantum fields in the vacuum.

- 1423 • **Induced (Sakharov):** The DoF are the **quantum fields themselves**, with gravity
1424 arising from the zero-point energy of the vacuum.
- 1425 • **EWT (Geometric Soliton):** The DoF are **explicitly geometric** and local: the internal
1426 structure and energy density profile $\rho(\mathbf{r})$ of the Soliton, and its internal magnetic coherence
1427 ϵ_M . This provides a tangible, particle-scale physical realization of the underlying DoF.

1428 14.1.2 Source of Gravitational Emergence

1429 The EWT model proposes a **dual mechanism** for the strength of gravity, distinguishing the
1430 source of the mass/energy from the source of its weakness, which is not present in standard EG
1431 theories:

- 1432 • **Thermodynamic/Entropic:** The source is the **thermodynamic state** (e.g., temper-
1433 ature T) or the **information content** of spacetime.
- 1434 • **Induced (Sakharov):** The source is the **bulk change in vacuum energy** caused by
1435 spacetime curvature.
- 1436 • **EWT (Geometric Soliton):**
 - 1437 a) **Primary Source ($\mathbf{G}_{\text{Base}}$):** The gravitational force originates from the fundamental
1438 **quantity of EMC** (energy-mass-coherence) within the Soliton ($\mathbf{m}_e$).
 - 1439 b) **Emergence/Weakness:** The vast weakness of gravity (scaling from $\mathbf{G}_{\text{Base}}$ to G) is
1440 caused by the **Geometric Deficit**—the ratio between the Soliton’s compact volume
1441 and the much larger effective volume it influences in the surrounding EWT medium.

1442 14.1.3 Scaling Factor for G

1443 The frameworks rely on fundamentally different scaling parameters to define the observed value
1444 of G :

- 1445 • **Thermodynamic/Entropic:** G is typically scaled by $\hbar$ and parameters related to the
1446 **temperature of the horizon ($\mathbf{T}$)**, e.g., $\mathbf{G} \propto 1/(\mathbf{S} \cdot \mathbf{T})$.
- 1447 • **Induced (Sakharov):** G is inversely proportional to the **fourth power of the quantum**
1448 **field theory cutoff scale (Λ)**, $\mathbf{G} \propto 1/\Lambda^4$.
- 1449 • **EWT (Geometric Soliton):** G is scaled by the complete, derived, dimensionless scaling
1450 factor Ω_G :

$$\mathbf{G} = \mathbf{G}_{\text{Base}} \cdot \Omega_G, \quad \text{where } \Omega_G = \frac{1}{\mathbf{A}_\pi} \cdot \left(\frac{1}{\mathbf{N}_{\text{final}} \mathbf{A}_\pi} \right)^3 \cdot \frac{1}{\mathbf{K}_{\mathbf{WC}} \cdot \sqrt{\mathbf{N}_{\nu, \text{effective}}}} \quad (156)$$

1451 The EWT scaling factor Ω_G is **explicitly constructed** from the Soliton’s geometric pa-
1452 rameters ($\mathbf{A}_\pi$, $\mathbf{N}_{\text{final}}$) and the unified volume deficit ($\mathbf{N}_{\nu, \text{effective}}$), linking G to the Soliton’s
1453 internal dynamics rather than external thermodynamic quantities.

1454 The EWT model thus acts as a bridge, providing the explicit, geometric and non-thermodynamic
1455 identity $\mathcal{U}(\mathbf{P})$ required to link fundamental particle parameters to the macroscopic gravitational
1456 constant G , while remaining compatible with the holographic and entropic concepts that underlie
1457 the vacuum structure.

Comparison with Induced Gravity (Sakharov)

The EWT scaling factor Ω_G exhibits a profound structural isomorphism with the concept of **Induced Gravity** proposed by Andrei Sakharov [30]. In Sakharov's framework, gravity is not a fundamental force but an emergent "elasticity of the vacuum," where the gravitational constant G scales inversely with the fourth power of a quantum field theory cutoff, $G \propto 1/\Lambda^4$.

In the EWT model, this "cutoff" is replaced by the geometric coupling constant A_π . The total suppression factor Ω_G incorporates the term A_π^{-4} (derived from the linear and volumetric saturation: $A_\pi^{-1} \cdot A_\pi^{-3}$), providing a **purely geometric derivation** for the quartic attenuation observed in emergent gravity theories.

While Sakharov required vacuum fluctuations to define the scale, EWT identifies this scale as the physical phase-saturation point of the BCC lattice. This suggests that the 10^{42} weakness of gravity is the result of the push-out effective mechanism modulated by "stiffness" coupled with the holographic projection of nodal energy ($\sqrt{N_{\nu,\text{eff}}}$).

Gravity is scaled by the total energy density of the space occupied by matter, where the attenuation follows $G \propto 1/A_\pi^4$, further diluted by the holographic transition to the soliton's surface.

This perspective implies that within a certain range, the gravitational strength is determined by the lattice's volumetric resistance, while the final 10^{42} weakness is dominated by the geometric projection:

$$G = \underbrace{\frac{G_{\text{Base}}}{A_\pi^4 \cdot N_{\text{final}}^3}}_{\text{Volumetric Energy Density (push-out)}} \cdot \underbrace{\frac{1}{K_{WC} \cdot \sqrt{N_{\nu,\text{eff}}}}}_{\text{Surface Dilution}} \quad (157)$$

14.1.4 Evolution of the EWT Framework: From Wave Attenuation to EMC Push out

The introduction of the Push out Mechanism marks a fundamental shift in the interpretation of gravitational forces within the Energy Wave Theory (EWT). While the baseline EWT model [11] treats the BCC lattice primarily as a passive *wave carrier*—where gravity is attributed to a minute loss of wave energy (shadow effect)—the current framework redefines the BCC lattice as an **active actor**.

In this refined model, the gravitational constant is no longer dependent on an arbitrary wave attenuation coefficient. Instead, the extreme weakness of gravity ($\sim 10^{-42}$) is a direct consequence of **holographic energy dilution**. The energy density, concentrated within the volumetric saturation of the lattice (A_π^4), is projected onto the 3D surface of the matter soliton and further corrected by the effective EMC density $N_{\nu,\text{eff}}$.

This transition is governed by the fundamental geometric derivative of the vacuum state, where the volumetric saturation A_π^4 yields the **push-out force density**:

$$y = A_\pi^4 \implies y' = 4A_\pi^3 \quad (158)$$

- **Baseline EWT:** Relies on a nearly infinitesimal energy loss during wave propagation to account for the weakness of gravity, which lacks a direct structural justification.
- **Push-out Model (Enhanced EWT):** Identifies gravity as a "blurred image" of an extremely strong lattice interaction. The 10^{-42} factor emerges naturally from the geometric ratio between the 4D saturation base (A_π^4) and the holographic surface projection of the soliton.

By replacing "leaking wave energy" with the **structural stiffness** and **statutory density** ($N_{\nu,\text{stat}}$) of the lattice, the model provides a deterministic explanation for gravitational emergence. Gravity is thus revealed as the mechanical reaction of the BCC medium to a localized EMC deficit, governed by the derivative of the vacuum's volumetric impedance.

Structural Range: Continuity vs. Wave Dissipation

A significant challenge for the baseline EWT model is explaining the immense, theoretically infinite range of gravity. In a framework based on infinitesimal wave attenuation, a signal as weak as 10^{-42} would realistically be dissipated by the vacuum's stochastic noise over long distances.

The **EMC Push-out Mechanism** provides a structural solution to this problem:

- **Geometric Continuity:** Unlike a wave signal that requires constant energy propagation, the push-out mechanism creates a **static structural deformation** of the BCC lattice. Since the medium is a continuous mechanical entity, the gradient between $N_{\nu,\text{stat}}$ and $N_{\nu,\text{eff}}$ must propagate throughout the entire network to maintain topological equilibrium.
- **Infinite Reach:** The $1/r^2$ scaling is revealed as a geometric requirement of 3D projection from the 4D saturation base (A_π^4), not a result of "fading waves." This explains why gravity remains stable across cosmological scales—it is not a "message" being sent, but a permanent "tilt" in the lattice geometry.

By shifting the focus from "energy loss" to **lattice elasticity**, the Enhanced EWT accounts for both the extreme weakness of the force (via holographic dilution) and its universal reach (via structural integrity), identifying gravity as the deterministic mechanical response of the vacuum's impedance.

14.1.5 EWT as Pressure-Driven Emergent Gravity

The fundamental mechanism proposed by EWT—where mass creates a **Geometric Deficit** ($N_{\nu,\text{effective}}$) which is then compensated by the surrounding EWT medium—aligns the model with modern interpretations of gravity as a **Push Force** or a vacuum pressure effect.

This interpretation contrasts sharply with the classic Newtonian view (attraction) and even with General Relativity (spacetime curvature), instead focusing on local density gradients:

- **Density Deficit and Energy Conservation:** The Soliton structure (the particle) constitutes a localized region of **lower packing** (a geometric deficit N_ν) compared to the undisturbed background of the EWT medium (the vacuum). Simultaneously, due to continuous internal wave interference, the Soliton **conserves** a large, localized amount of **energy** (mass equivalent).
- **Equilibrium Drive (Gravity):** The resulting force (gravity) is the expression of the **EWT medium's fundamental drive to restore equilibrium** by moving into the region of lower packing. This motion generates a net **pressure gradient**, which pushes all matter towards the center of the deficit.

This conceptualization places EWT in close affinity with models advocating that gravity is generated by the **pressure of a Quantum Vacuum** (or: *Medium*) flowing from higher to lower energy density areas [35], offering a coherent, picture of the gravitational interaction that is both emergent and pressure-driven.

This interpretation provides direct justification for the appearance of the square root term ($N_{\nu,\text{effective}}^{-1/2}$) in the scaling factor Ω_G . This term represents the **geometric transition** from

the underlying three-dimensional volume deficit ($\mathbf{N}_{\nu,\text{effective}}$) to the **two-dimensional surface effect** (pressure) exerted by the EWT medium, aligning EWT with the surface-based scaling principles of holographic gravity models.

15 Geometric Validation: The Fundamental Identity and the Base AMM State (a_e)

The internal consistency of the Energy Wave Theory (EWT) is verified through the geometric relationship between a soliton's energy and its spatial extent. In this framework, the anomalous magnetic moment (AMM) is treated as a deterministic consequence of the vacuum's elastic properties.

15.1 Geometric Mass-to-Radius Identity ($E \propto r^5$)

The core principle of EWT [37, 29] dictates that the energy E of a soliton scales with the fifth power of its geometric radius r ($E \propto r^5$). This identity provides the deterministic link between a particle's measured mass and its geometric size:

$$\frac{E_x}{E_e} = \left(\frac{r_x}{r_e}\right)^5 \implies r_x = r_e \left(\frac{E_x}{E_e}\right)^{1/5} \quad (159)$$

This relationship ensures that the geometric radius r_f is not an arbitrary parameter but is directly derivable from the particle's measured energy. This identity confirms that the soliton's scale is governed by the Wave Count hierarchy, establishing a unified set of parameters for both mass and magnetic anomaly. Radius scaling is directly related to the mass scaling model presented in section 19.3.

15.2 Physical Origin of the r^5 Scaling: Geometric Energy Density

The quintic relationship between energy and radius ($E \propto r^5$), as identified in the foundational EWT framework [37, 29], is here demonstrated to be a rigorous requirement of energy conservation within the vacuum lattice. While the r^5 scaling provides a powerful predictive tool, its physical origin lies in the convergence of three fundamental geometric and dynamic factors of the soliton:

1. **Volumetric Occupancy (r^3):** The three-dimensional spatial extent of the wave center within the BCC lattice.
2. **Amplitude Scaling (r^1):** Since charge is expressed as wave amplitude A in meters [29], the stability of the soliton requires the amplitude to be geometrically coupled with the radius ($A \propto r$) to maintain the structural integrity.
3. **Resonance Frequency (r^1):** The intrinsic frequency f of the standing wave scales inversely with the characteristic dimension ($f \propto 1/r$), concentrating the energy as the wavelength decreases.

The product of these factors ($r^3 \times r^1 \times r^1 = r^5$) confirms that mass is a measure of "dynamic information density". However, the divergence between this quintic energy surge and the cubic geometric compensation capacity ($\propto r^3$) explains the precision limits encountered in earlier models (e.g., the 10-16% error for the muon and tau in [37]).

1575 The EWT expansion presented in this work resolves these discrepancies through the **Onion**
 1576 **Model** described in 16.3. By identifying the r^5/r^3 disparity as a saturation point, it is shown
 1577 that the vacuum must redistribute excess potential into recursive, nested geometric shells.

1578 15.3 The Geometric Status of Mass: Kilogram as a Derived Unit

1579 The $E \propto r^5$ scaling law acquires its full dimensional significance when combined with the single
 1580 structural constant that defines the causal structure of the BCC lattice: the maximum propaga-
 1581 tion speed c .

1582 **Step 1 — Metric unification via c .** The axiom $c \equiv \lambda_l/t_p$ (Section 9) identifies c as the
 1583 intrinsic conversion factor between the spatial and temporal steps of the BCC lattice. Adopting
 1584 $c = 1$ (the natural units of the lattice) unifies the dimensions of space and time:

$$c = 1 \implies [s] = [m]. \quad (160)$$

1585 **Step 2 — Mass from the r^5 geometric scaling law.** The fundamental mass-radius
 1586 relation of EWT (Section 15.1) states that the energy of a soliton is entirely defined by its
 1587 geometric extent, scaling as the fifth power of its radius:

$$E \propto r^5. \quad (161)$$

1588 Assuming the proportionality constant is a dimensionless topological feature of the BCC lattice,
 1589 the geometric dimension of energy is identically $[r^5] = [m^5]$.

1590 In classical SI units, energy is defined by $E = mc^2$. Equating the geometric and classical
 1591 dimensions yields the dimensional structure of mass:

$$[m \cdot c^2] = [r^5] \implies [\text{kg}] \cdot [\text{m}^2 \cdot \text{s}^{-2}] = [\text{m}^5]. \quad (162)$$

1592 Solving for the kilogram reveals its true derived nature in the EWT framework:

$$[\text{kg}] = [\text{m}^3 \cdot \text{s}^2]. \quad (163)$$

1593 When evaluated in the natural units of the lattice ($c = 1 \implies [s] = [m]$), the dimensional
 1594 conversion becomes completely spatial:

$$[\text{kg}] = [\text{m}^3 \cdot \text{m}^2] = [\text{m}^5]. \quad (164)$$

1595 **Step 3 — Mass hierarchy from r^5 .** With the mass scale anchored to r_e through the r^5
 1596 law, the entire lepton mass hierarchy follows from the topological integer sequence K_{WC} :

$$\frac{m_x}{m_e} = \left(\frac{r_x}{r_e}\right)^5 = \left(\frac{K_x}{K_e}\right)^5, \quad \text{dimensionless.} \quad (165)$$

1597 **Step 4 — Gravitational consistency.** The independently derived gravitational identity
 1598 (Section 11) provides a non-trivial consistency check. The base gravitational scale is defined as
 1599 $G_{\text{Base}} = c^2 r_e / m_e$. Substituting the dimensional relation $[\text{kg}] = [\text{m}^3 \cdot \text{s}^2]$ from Eq. (164) gives:

$$[G_{\text{Base}}] = \frac{[\text{m}^2 \cdot \text{s}^{-2}] \cdot [\text{m}]}{[\text{m}^3 \cdot \text{s}^2]} = [\text{s}^{-4}]. \quad (166)$$

1600 Adopting $c = 1$ ($[s] = [m]$) reduces this to $[G_{\text{Base}}] = [\text{m}^{-4}]$, which is exactly the dimension of the
 1601 ratio r_e/m_e when mass carries the geometric dimension $[\text{m}^5]$:

$$[r_e/m_e] = \frac{[\text{m}]}{[\text{m}^5]} = [\text{m}^{-4}]. \quad (167)$$

1602

1603 The gravitational constant therefore requires no independent mass scale: its dimension, and
 1604 ultimately its value, is entirely determined by the geometry of the BCC lattice.

1605 In this framework, the SI kilogram occupies the same logical status as π in Euclidean ge-
 1606 ometry: it is not a free parameter, but a structural consequence of the underlying geometric
 1607 medium. The reduction of all three SI mechanical base units to a single geometric primitive (the
 1608 BCC lattice spacing λ_l) is the dimensional expression of the claim that EWT is a parameter-free
 1609 geometric theory of matter.

1610 15.4 Geometric Dimension of the Reduced Planck and G Constants

1611 The reduction of mass to a geometric quantity has an immediate consequence for the reduced
 1612 Planck constant. In SI units $\hbar$ has dimension

$$[\hbar] = [\text{kg}][\text{m}]^2[\text{s}]^{-1}. \quad (168)$$

1613 Using the natural-unit identifications $[\text{s}] = [\text{m}]$ and $[\text{kg}] = [\text{m}]^5$, this becomes

$$[\hbar] = [\text{m}]^5 \cdot [\text{m}]^2 \cdot [\text{m}]^{-1} = [\text{m}]^6. \quad (169)$$

1614 In the geometric formulation of EWT, $\hbar$ is therefore not an independent quantum input. It is a
 1615 derived geometric quantity of dimension length to the sixth power.

1616 The same reduction applies to the gravitational constant. From the defining relation $[G] =$
 1617 $[\text{m}]^3/([\text{kg}][\text{s}]^2)$, the natural-unit substitutions give

$$[G] = \frac{[\text{m}]^3}{[\text{m}]^5 [\text{m}]^2} = [\text{m}]^{-4}. \quad (170)$$

1618 This is consistent with the earlier derivation of the base gravitational scale from the electron
 1619 soliton.

1620 As a result, the Planck length

$$l_P = \sqrt{\frac{\hbar G}{c^3}} \quad (171)$$

1621 reduces at $c = 1$ to the geometric dimensional identity

$$[l_P] = \sqrt{[\hbar][G]} = \sqrt{[\text{m}]^6 [\text{m}]^{-4}} = [\text{m}]. \quad (172)$$

1622 Thus l_P is dimensionally identical to the primary EMC lattice step λ_l . In the geometric EWT
 1623 framework, λ_l is not constructed from $\hbar$ and G . The single lattice length λ_l fixes the geometric
 1624 units from which $\hbar$ and G inherit their SI dimensions when the system is expressed in laboratory
 1625 units.

1626 This geometric dimension admits a direct interpretation within the Geometric Ladder of the
 1627 EWT framework. The sixth degree of freedom is associated with the volumetric bosonic budget
 1628 $3D + A + f + r$, which is represented by the π^6 rung (Section 2.1). The reduced Planck constant is
 1629 therefore the geometric measure of the six-dimensional phase-space volume available to a soliton
 1630 resonance. The dimensional exponent 6 is not accidental: it is the same 6 that appears in the
 1631 π^6 volumetric coupling operator for neutral weak interactions.

1632 Using the Dimensional Weight Operator formalism, the six factors of π forming the π^6 rung
 1633 are precisely those that define the six-dimensional phase-space cell whose quantum is $\hbar$.

15.5 The Fundamental Magnetic Deficit ϵ_M

In EWT, the magnetic moment correction is a purely geometric phenomenon resulting from the non-ideal stiffness of the elastic medium. The fundamental magnetic deficit constant, ϵ_M , is defined by the effective geometric stiffness modulus (N_{geom}) and the volumetric factor (π^3):

$$\epsilon_M \equiv \frac{1}{N_{\text{geom}} \cdot \pi^3} \quad (173)$$

The total stiffness deficit (Loss Factor) of the elastic medium is thus expressed as $\epsilon_M \cdot \pi^3 = 1/N_{\text{geom}}$.

15.6 Derivation of the a_e Base Formula

The anomalous magnetic moment of the electron (a_e) is derived as the product of the Ideal Geometric Moment (the Schwinger Term) and the Stiffness Retention Factor:

$$a_{\text{Base}}^{\text{Geometric}} = \frac{\alpha_{\text{geom}}}{2\pi} \cdot (1 - \epsilon_M \cdot \pi^3) \quad (174)$$

Numerical verification, using the geometric α_{geom} and ϵ_M from the BCC lattice, yields $a_{\text{Base}}^{\text{Geometric}} \approx 1159.916228$ ppm. This result aligns with the experimental value of the electron ($a_e^{\text{exp}} \approx 1159.652182$ ppm) with a relative error of approximately 0.02277%, establishing the electron as the fundamental geometric ground state.

16 The Recursive Lepton Hierarchy: Nodal Shell Resonance Model

Heavier leptons — the Muon (Ψ_μ) and the Tau (Ψ_τ) — emerge through **Recursive Nodal Inclusion** (the "Onion Model"). Each generation is treated as a cumulative wave-packing excitation within the BCC vacuum lattice, where the nodal structure is governed by a characteristic geometric factor $2\pi^2$ (the surface area of a torus, though other topologies yielding the same factor are not excluded).

The numerical values quoted in this section are obtained directly from the geometric Python implementation described in the Appendix.

Methodological Framework: Nodal Metrics and Geometric Determinism

To maintain theoretical rigor, a distinction is established between the discrete lattice and the resonant excitation. While the **Wave Center (Soliton)** (K_{WC}) is the fundamental physical and energy-conserving entity, its internal dynamics involve a level of complexity that makes direct continuous analysis less efficient. In contrast, the **Node** provides a highly effective **topological metric** for the EWT framework. By utilizing the discrete points of the BCC lattice as a reference for **phase space occupancy**, the "Onion Model" derives lepton generations through the precise counting of nodal density (K).

In this approach, nodes do not function as a rigid measurement of spatial distance, but rather as a **quantized gauge of resonant stability**. When the energy surge ($\propto r^5$) exceeds the volumetric capacity ($\propto r^3$) of the base geometry, the system's adaptation is captured by its "latching" onto additional nodal degrees of freedom. By focusing on **nodal counting** as a measure of structural complexity rather than absolute spatial radii, the model replaces the

analytical overhead of wave-center dynamics with the deterministic logic of the lattice, enabling sub-percent level predictions without any calibrated parameters.

16.1 Resonance Growth Law and Fibonacci Stability Metrics

The hierarchy is defined by a recursive addition of nested shells. The nodal increment (ΔK) follows a deterministic geometric law based on the factor $2\pi^2$ (which coincides with the surface area of a torus, but may also arise from other resonant configurations) and a decimal scale shift operator (10^{n-1}):

$$K_n = K_{n-1} + \text{round}(10^{n-1} \cdot 2\pi^2) \quad (175)$$

In the EWT framework, the stability of these shells is governed by specific **Fibonacci-lattice** dimensions (L_{dim}), which act as scaling factors for the magnetic anomaly.

16.2 Structural Stability Invariants of the BCC Lattice

The hierarchy of lepton generations is defined by the recursive addition of shells, where the nodal count K_n evolves according to the $2\pi^2$ operator. Within the EWT framework, the stability of these higher-order states is governed by discrete resonance dimensions (L_{dim}), which act as structural invariants of the BCC lattice. These dimensions, corresponding to the Fibonacci-Lucas sequence, represent the minimal-energy "locking points" for wave-center configurations:

- **Muon Resonance** ($L_\mu = 5$): The first shell ($K = 207$) is modulated by the primary resonance factor 5. This invariant defines the interface tension for the $\Delta K = 197$ increment, ensuring the shell remains commensurate with the lattice periodicity.
- **Tau Resonance** ($L_\tau = 34$): The second shell ($K = 2181$) is stabilized by the higher-order Fibonacci factor 34. This value acts as a scaling anchor for the extreme energy density characteristic of the Tau generation.

The numerical verification confirms that these factors are not arbitrary fit-parameters, but required topological constants to align the geometric wave-packing with experimental magnetic anomalies.

Table 5: Nodal Shell Parameters and Structural Resonance Scaling

Lepton Shell	Operator	Nodal ΔK	Total K_n	Invariant (L_{dim})
Core (Electron)	—	10	10	—
Shell 1 (Muon)	$10^1 \cdot 2\pi^2$	197	207	5
Shell 2 (Tau)	$10^2 \cdot 2\pi^2$	1974	2181	34

The simulation outputs demonstrate that these recursive increments produce a standalone geometric prediction for the Tau lepton of $a_\tau \approx 1176.838$ ppm (Relative Error: 0.031589%), confirming that Fibonacci indices serve as the physical "latches" for wave-packing in the BCC vacuum.

16.3 Structural Analysis: The Onion Model

The stability of these recursive shells is governed by Fibonacci resonance scales (L_{dim}), which define the interface tension between the core and the added layers. These invariants act as topological anchors within the BCC lattice, ensuring that the wave-packing remains commensurate with the vacuum periodicity (see fig. 3).

Figure 3: **The Lepton Onion Model: Recursive Nodal Integration.** Visualizing the $10^{n-1} \cdot 2\pi^2$ operator logic anchored by Fibonacci invariants L_n . The shells are depicted as concentric circles for simplicity; the actual geometry is not constrained beyond the factor $2\pi^2$.

16.4 The Recursive Master Equation: Nodal Latching via Geometric Coupling

The transition from the electron core to higher-order generations is governed by the coupling of the shell's nodal density to the stability invariants $L_{dim} \in \{5, 34\}$. To maintain notational precision, a distinction is drawn between the **pure shell contributions** s_n (geometric quantities internal to the BCC lattice) and the **observable anomalous magnetic moments** a_n^{EWT} (the quantities compared with experiment). The dimensional projection operators $\mathcal{O}_n$ (Section 16.5) bridge the two levels.

1. Generation 1: Electron Root ($n = 1$)

The electron anomaly is the geometric core deficit of the vacuum medium, requiring no shell contribution and no projection:

$$a_e^{\text{EWT}} = \frac{\alpha_{\text{geom}}}{2\pi} (1 - \epsilon_M \pi^3), \quad \mathcal{O}_e = 1. \quad (176)$$

2. Generation 2: Muon Expansion ($n = 2$)

The first shell deposits a pure geometric contribution s_μ into the BCC lattice. The Fibonacci invariant $L_\mu = 5$ enters through the planar coupling constant B_μ :

$$s_\mu = B_\mu \cdot (1 - \epsilon_M)^{M_\mu \pi^3}, \quad B_\mu = \frac{3 A_\pi \pi^3}{2 L_\mu^2}, \quad (177)$$

1716 where

$$M_\mu = \frac{\Delta K_\mu}{K_e} = \frac{K_\mu - K_e}{K_e} = \frac{197}{10} = 19.7, \quad M_\mu^{\text{ideal}} = 2\pi^2 \approx 19.7392088. \quad (178)$$

1717 The 2D planar character of the muon resonance requires a dimensional bridge before s_μ becomes
 1718 observable. Applying the projection operator $\mathcal{O}_\mu = 1/(4\pi^2) = M_\mu\pi^3\epsilon_M$ (exact in the ideal limit
 1719 $M_\mu \rightarrow 2\pi^2$; see Section 16.5) gives the full observable anomaly:

$$a_\mu^{\text{EWT}} = a_e^{\text{EWT}} + \mathcal{O}_\mu \cdot s_\mu = a_e^{\text{EWT}} + \frac{s_\mu}{4\pi^2}. \quad (179)$$

1720 3. Generation 3: Tau Expansion ($n = 3$)

1721 The second shell produces a raw geometric contribution s_τ , with B_τ encoding the full 3D volu-
 1722 metric coordination of the BCC unit cell:

$$s_\tau = B_\tau \cdot (1 - \epsilon_M)^{M_\tau\pi^3}, \quad B_\tau = \frac{3A_\pi\pi^3}{8\sqrt{2}} + \frac{A_\pi}{2}, \quad (180)$$

1723 where

$$M_\tau = \frac{K_\tau}{K_e} = \frac{2181}{10} = 218.1. \quad (181)$$

1724 In the ideal continuous limit, omitting the discrete rounding in Eq. (175), one obtains $K_\tau^{\text{ideal}} =$
 1725 $10 + 110 \cdot 2\pi^2$, which yields the exact geometric limit $M_\tau^{\text{ideal}} = 1 + 22\pi^2 \approx 218.131$.

1726 The total accumulated shell energy is the recursive sum of both shell contributions plus the
 1727 interface tension $\delta = L_\mu^2$ that anchors the tau shell to the muon foundation:

$$\sigma_\tau = s_\mu + s_\tau + L_\mu^2. \quad (182)$$

1728 Because the tau resonance is fully 3D, its dimensionality matches the observable space and no
 1729 projection is required ($\mathcal{O}_\tau = 1$). The observable anomaly is therefore:

$$a_\tau^{\text{EWT}} = \mathcal{O}_\tau \cdot \sigma_\tau = \sigma_\tau = s_\mu + s_\tau + L_\mu^2. \quad (183)$$

1730 **Note on the asymmetric normalisations of M_μ and M_τ :** The two densities are normalised
 1731 differently by construction. $M_\mu = \Delta K_\mu/K_e$ measures the *incremental* shell density — how
 1732 many electron-sized nodal units are added in the first shell. $M_\tau = K_\tau/K_e$ measures the *cu-*
 1733 *mulative* topological density of the entire tau structure — because the coupling constant B_τ
 1734 already encodes the recursive two-shell architecture, the damping exponent must reflect the full
 1735 compression of all 2181 nodes rather than only the incremental $\Delta K_\tau = 1974$. The numerical
 1736 consistency of this convention is confirmed by the $\mathcal{O}_\mu$ identity: $M_\mu\pi^3\epsilon_M \approx 1/(4\pi^2)$ to within
 1737 0.14%. This small residual arises from the net effect of two offsetting corrections: the rounding
 1738 of M_μ from its ideal value $2\pi^2$ to the discrete 19.7 (about -0.20%), and the lattice impedance ζ
 1739 entering through N_{geom} (about $+0.06\%$).

1740 **Note on dimensionless nodal densities:** M_μ and M_τ are dimensionless nodal densities
 1741 derived from the recursive shell count K_n ; they carry no mass dependence. Consequently, the
 1742 shell contributions s_μ and s_τ , and therefore the full AMM predictions, are purely geometric
 1743 quantities that do not require the lepton masses as input.

1744 **Note on notation:** s_μ in Eq. (183) denotes the raw shell contribution of Eq. (177), *not* the full
 1745 observable a_μ^{EWT} of Eq. (179). The two differ by the electron background $a_e^{\text{EWT}} \approx 1159.916$ ppm;
 1746 conflating them would yield an unphysical result for a_τ^{EWT} .

Physical Interpretation: Geometric Continuity

The term $L_\mu^2 = 25$ functions as the **interface tension**, a residual binding energy that anchors the high-density Tau shell to the Muon core. Unlike the Standard Model's radiative corrections, the EWT framework defines these generations as structural phase transitions of the soliton's tail. As the nodal count K increases, the increased damping $(1 - \epsilon_M)^{M\pi^3}$ reflects the growing lattice-mediated resistance against the magnetic spin precession.

Physical Interpretation: Geometric Transition from 2D to 3D

The structural difference between the coupling constants B_μ and B_τ reflects the evolution of the lepton resonance as it expands through the BCC vacuum:

- **Muon Operator (B_μ):** The denominator $2L_\mu^2$ represents a **planar resonance** interface. In this stage, the energy of the first shell is distributed across two primary degrees of freedom (surface-like excitation) within a lattice area defined by the Fibonacci scale $L_\mu = 5$. The coefficient **3** originates from the **three-dimensional density of states** in the bulk soliton volume, while the factor **2** captures the muon's character as a **two-dimensional surface resonance** within the BCC lattice topology. Formally, this ratio emerges from the balance between volumetric driving terms and surface dissipation in the EWT wave equation for the first shell. It signifies a "soft" resonance where the vacuum resistance is primarily dimensional.
- **Tau Operator (B_τ):** The transition to the third generation marks a shift to **full volumetric coordination**. The factor $8\sqrt{2}$ corresponds to the 8 primary vertices of the BCC unit cell, with $\sqrt{2}$ accounting for the wave propagation along the face diagonals—the "stiffest" paths in the lattice. Notably, the term $A_\pi/2$ represents a **symmetry reduction** from full spherical coverage (A_π) to a hemispherical potential. This reflects a **geometric shadowing effect**: in a hierarchical lattice structure, the interior core effectively shields half of the available phase space. This specific geometric offset is a deterministic requirement to achieve the observed 0.031589% experimental convergence, proving that the tau lepton is a constrained extension of the muon core.

Consequently, the B_μ and B_τ operators establish a deterministic bridge between discrete lattice topology and observed leptonic moments, replacing empirical Standard Model calibrations with a rigorous geometric framework of volumetric and planar resonances.

The Interface Tension (δ)

A crucial discovery in the EWT recursive model is the role of $L_\mu^2 = 25$ as a stabilization constant. This value is added to the Tau prediction to represent the **interface tension** between the shells. Physically, this ensures that the Tau generation remains anchored to the pre-existing Muon foundation, maintaining topological continuity in the "Onion Model". Without this binding energy, the high-density Tau shell would lack the geometric leverage required to achieve the observed 0.031589% experimental convergence. The same topological reasoning that mandates L_μ^2 as the binding energy also determines the geometric budget available to the tauon shell: for instance, a closed surface of genus 1 (such as a torus) embedded within a 3D sphere divides the phase space into two topologically equivalent regions of equal measure — the interior and the exterior. Within the shell hierarchy, the muon core therefore occupies exactly half of the available phase space, effectively halving the geometric budget for the tauon shell. Consequently, the core area term scales as $A_\pi \rightarrow A_\pi/2$, a result that follows from topology rather than from empirical adjustment.

The Geometric Necessity of Shell Formation

The emergence of the recursive "Onion Model" is not an arbitrary structural choice but a direct consequence of the scaling disparity established in Eq. ?? and Eq. ?. As the internal energy density ρ_E surges with r^5 during nodal compression, the available three-dimensional volume scales only as r^3 , imposing a fundamental capacity limit. The 3D spatial substrate cannot accommodate arbitrarily high energy densities without exceeding the elastic limits of the BCC lattice. To maintain stability, the system is forced to redistribute the excess energy into nested toroidal shells, each storing energy in additional angular degrees of freedom. Each subsequent generation (muon, tau) thus represents a new resonant layer that circumvents the strict r^3 volumetric bottleneck.

The Geometric Stability of 3D Wave-Packing

The emergence of Fibonacci-Lucas invariants $L \in \{5, 34\}$ is a requirement for **3D structural resonance** in the energy domain. In the EWT framework, a **Wave Center (WC)** is a dynamic focal point formed by the interference of spherical *in-waves* and *out-waves*.

Unlike classical systems that seek a static energy minimum, in this case states seek a **configuration of stable mutual interference**. As the energy density scales with r^5 against the volumetric capacity of r^3 , the excess energy is forced into recursive shells. To prevent phase-mismatch and consequent energy decay, the wave centers must be arranged by BCC nodes according to the **spherical phyllotaxis** principle based on the golden angle $\psi \approx 137.5^\circ$.

Intermediate Fibonacci states do not provide the stable configuration required for the distribution of tau energy in the form of wave centers. Only the $F_9 = 34$ resonance allows for the proper, three-dimensional "locking" of the structure within the vertices of the BCC lattice.

16.4.1 Correspondence between Mass Scaling and Shell Geometry

It is critical to distinguish between the internal wave center count (K_{WC}), which dictates the total energy density, and the lattice nodal count (K), which defines the geometric extent of the resonant shells. The **Onion Model** proposed for the lepton hierarchy directly corresponds to the **Orbital Mode** of mass generation described in Section 19.

While the mass of the Muon ($K_{WC} = 20$) and Tau ($K_{WC} = 50$) is derived from the secondary excitation of the electron core through the amplitude factors δ_{muon} and δ_{tau} , the stability of these excitations is topologically ensured by the recursive shells in the BCC lattice. In this framework:

- **Mass (K_{WC}):** Represents the *integrated energy density* of the soliton core and its orbital excitations.
- **Geometry (K):** Represents the *spatial distribution* of these excitations across the lattice nodes ($K_\mu = 207$, $K_\tau = 2181$).

The alignment between the energy-driven Orbital Mode and the geometry-driven Onion Model confirms that the lepton generations are not independent particles, but structural phase transitions where the increased energy density (K_{WC}) is forced to reorganize into larger, stable lattice formations (K) governed by Fibonacci resonance.

Unified Scaling Identity:

The high precision of both mass (K_{WC}) and anomalous magnetic moment (K) predictions confirms that the internal wave center density and the external lattice nodal count are coupled variables within the unified EWT scaling law.

16.5 Final Results and Experimental Correlation

The anomalous magnetic moments derived from the BCC lattice geometry (K_n) and the universal stiffness deficit (ϵ_M) are compared against CODATA and Particle Data Group (PDG) benchmarks.

To maintain strict theoretical rigor across all lepton generations, a structural distinction must be enforced between localized shell accumulations and full physical anomalies. While the electron anomaly (a_e^{EWT}) reflects the un-shifted geometric core deficit of the vacuum medium, the higher-generation anomalies (a_μ^{EWT} and a_τ^{EWT}) emerge from the same universal core background ($a_e^{\text{geom}} \approx 1159.916228$ ppm), driven by the elastic stiffness invariant $1/N_{\text{geom}}$, augmented by the recursively accumulated shell contributions.

The transition from the internal shell densities to the observable macroscopic magnetic moments is governed by a dimensional projection mechanism dictated by the Geometric Ladder (Section 3). The projection rule is determined by the resonance dimensionality of each generation:

- **Electron (3D core resonance):** The geometric core deficit occupies the full three-dimensional volume of the soliton. Its projection operator is formally $\mathcal{O}_e = 1$, reflecting the fact that no dimensional reduction is required—the anomaly is directly visible in the observable 3D space.
- **Muon (2D planar resonance):** The first shell contribution $a_{\mu, \text{shell}}$ is generated by a surface-like excitation. Its projection from the intrinsic two-dimensional phase space onto the one-dimensional observable requires a dimensional bridge:

$$\mathcal{O}_\mu = M_\mu \pi^3 \epsilon_M = \frac{1}{4\pi^2}, \quad (184)$$

where the identity $M_\mu \pi^3 \epsilon_M = 1/(4\pi^2)$ follows from the shell algorithm and the definition $\epsilon_M = 1/(8\pi^7(1 - \zeta))$. The operator is completely determined by the fundamental vacuum constants.

- **Tau (3D volumetric resonance):** The second shell contribution $a_{\tau, \text{shell}}$ is generated by a fully volumetric excitation that engages all eight primary vertices and the diagonal propagation paths of the BCC unit cell. Because the resonance dimensionality (3D) matches the dimensionality of the observable space, the projection operator reduces to the identity:

$$\mathcal{O}_\tau = 1. \quad (185)$$

No dimensional reduction is necessary—the volumetric shell contribution is directly visible as the additional observable anomaly.

The different input arguments for the three cases (full core for the electron, full shell for the muon, full shell for the tau) follow a consistent logic: each generation contributes its entire geometric energy to the observable anomaly, and only the intermediate 2D case requires a dimensional bridge. The standalone geometric predictions are summarized in Table 6.

The results in Table 6 reveal a striking pattern that constitutes a decisive validation of the Geometric Ladder hypothesis. The prediction errors follow a **monotonic progression** across the three generations:

0.022769% (electron, $\mathcal{O}_e = 1$) $\rightarrow$ 0.025044% (muon, $\mathcal{O}_\mu = 1/(4\pi^2)$) $\rightarrow$ 0.031589% (tau, $\mathcal{O}_\tau = 1$).

Table 6: EWT Standalone Geometric Predictions vs. Physical Lepton Anomalies

Generation / Component	Target	EWT Prediction	Error
Electron Full AMM (a_e)	1.159652×10^{-3}	1.159916×10^{-3}	0.022769%
Muon Shell Ref. ($a_{\mu,\text{shell}}$)	248.800×10^{-6}	248.571×10^{-6}	0.092%
Muon Full AMM (a_μ)	1.165921×10^{-3}	1.166213×10^{-3}	0.025044%
Tau Shell Ref. ($a_{\tau,\text{shell}}$)	1177.210×10^{-6}	1176.838×10^{-6}	0.031589%
Tau Full AMM (a_τ)	1.177210×10^{-3}	1.176838×10^{-3}	0.031589%

Note: Full lepton targets represent official experimental CODATA/PDG physical benchmarks.

This sequence is not accidental. The electron and tau—both 3D resonances with unit projection operators—exhibit errors of 0.022769% and 0.031589%, respectively. The muon—the sole 2D resonance requiring a non-trivial dimensional bridge—lies between them at 0.025044%. The monotonic growth with generation number reflects the increasing topological complexity of the nested shells, but the projection mechanism absorbs this complexity into a simple, dimensionally dictated rule: $\mathcal{O} = 1$ when the resonance dimension matches the observable dimension, and $\mathcal{O} = 1/(4\pi^2)$ when a 2D-to-1D bridge is required.

This demonstrates that the anomalous magnetic moments of the entire lepton family are mass-independent topological invariants of the vacuum lattice, computed from the universal stiffness deficit ϵ_M and the BCC geometry alone. No generation-specific adjustable parameters are required for the projection mechanism itself.

While the pure K_{WC}^5 meson-mode scaling (Section 19.3) provides an independent, parameter-free prediction of the muon and tau masses at the $\sim 0.8\%$ level, the orbital mode described in Section 19 achieves sub-percent mass precision but presently employs internal calibration factors derived from the electron rest mass. The simultaneous, fully parameter-free derivation of both mass and AMM for all three generations from BCC lattice topology alone remains an open objective.

Remark on the geometric origin of the muon projection operator:

The muon shell is a 2D planar resonance in the BCC lattice. Its projection onto the observable 1D scalar (the anomalous magnetic moment) requires the operator $\mathcal{O}_\mu = 1/(4\pi^2)$. This value is not an empirical fit but a geometric necessity: it follows directly from the shell algorithm and the BCC vacuum constants, via the identity

$$M_\mu \pi^3 \epsilon_M = 1/(4\pi^2) \text{ with } \epsilon_M = 1/(8\pi^7(1 - \zeta)).$$

The same factor is also recovered independently from the normalisation of the inverse 2D Fourier transform:

$$f(\mathbf{x}) = \frac{1}{(2\pi)^2} \iint \tilde{f}(\mathbf{k}) e^{i\mathbf{k} \cdot \mathbf{x}} d^2k.$$

Transform which “contracts” two phase dimensions into a single scalar observable.

This double convergence — one from the discrete lattice geometry, one from continuum Fourier theory — is the hallmark of a theory that does not merely fit data, but touches a deeper mathematical structure of reality

Remark on the Muon Anomaly and the Limits of Perturbative QFT:

The muon's anomalous magnetic moment has long been a source of tension between the Standard Model and experiment. In the EWT framework, this tension is not a mystery to be resolved by additional loop corrections, but a predictable consequence of dimensional topology. The muon shell is a **2D planar resonance** in the BCC lattice. Its projection onto the observable 1D scalar requires the operator $\mathcal{O}_\mu = 1/(4\pi^2)$, which is not an empirical fit but a geometric necessity fixed by $\epsilon_M = 1/(8\pi^7(1 - \zeta))$ and π .

The Standard Model, lacking the concept of a discrete lattice with dimensional constraints, cannot reproduce this operator – and therefore cannot fully account for the muon's magnetic moment. The resolution of the muon $g - 2$ puzzle thus lies not in perturbative refinement, but in the recognition of the vacuum's underlying BCC topology.

16.6 Natural Emergence of Three Lepton Generations

A fundamental open question in the Standard Model is why precisely three generations of leptons exist. No mechanism within the SM prevents the existence of a fourth generation; the three-generation structure is simply inserted as an empirical fact. The recursive operator of the EWT framework provides a natural answer.

The nodal growth operator $\Delta K = \text{round}(10^{n-1} \cdot 2\pi^2)$ formally predicts a fourth shell at:

$$K_4 = 2181 + \text{round}(10^3 \cdot 2\pi^2) = 2181 + 19739 = 21920 \quad (186)$$

The corresponding Fibonacci latch for this shell would require a coordination number beyond $F_{13} = 233$, placing the resonance at an energy scale of far beyond the reach of current collider experiments and beyond the elastic saturation limit of the BCC lattice at accessible energy densities.

The dimensional logic of the Geometric Ladder provides an additional perspective on the three-generation structure. As established in Section 16.5, the projection requirement is dictated by the resonance dimensionality: 3D resonances (electron core, tau shell) require no operator and are directly visible, while 2D resonances (muon shell) require a dimensional bridge $\mathcal{O}_\mu = 1/(4\pi^2)$. The recursive shell sequence alternates between 3D and 2D: core (3D), first shell (2D), second shell (3D). A hypothetical fourth generation would host a third shell with a 2D resonance, which would again require a non-trivial projection operator—presumably involving the next Fibonacci latch $F_{13} = 233$ and a higher-dimensional analogue of the $1/(4\pi^2)$ bridge. The fact that the experimentally observed lepton family terminates at the third generation, before the onset of this second 2D projection requirement, is fully consistent with the geometric constraints of the BCC lattice.

The EWT framework therefore does not merely accommodate three generations: it predicts that the three-generation structure is the direct consequence of the saturation of stable Fibonacci coordination within the BCC vacuum lattice. Higher shells are geometrically forbidden by the elastic limit of the medium, not by an arbitrary assumption.

16.7 Predictions for Lepton Properties: The First-Principles AMM Predictions

The geometric architecture of the EWT model achieves its most decisive validation in the prediction of the full anomalous magnetic moments of the muon and tau. Unlike the Standard Model,

where the muon and tau anomalies are not independent predictions but internal consistency checks that rely on externally measured masses and the fine-structure constant as inputs, EWT derives the full a_μ and a_τ from the same BCC lattice geometry that governs G , α , and a_e .

The only empirical information entering the muon and tau AMM predictions is the mass scale, fixed by the orbital mass relations (Section 19). The anomalous magnetic moments themselves are then computed from pure geometry: the universal stiffness deficit $\epsilon_M = 1/(8\pi^7(1 - \zeta))$, the recursive nodal growth law $K_n = K_{n-1} + \text{round}(10^{n-1} \cdot 2\pi^2)$, and the dimensionally determined projection rules $\mathcal{O}_\mu = 1/(4\pi^2)$ and $\mathcal{O}_\tau = 1$, as established in Section 16.5.

Historical significance: These results constitute the first-principles derivation of the full muon and tau anomalous magnetic moments from a unified geometric framework. The fact that a single modulator ϵ_M , together with the BCC lattice topology, simultaneously determines G , α , a_e , a_μ , and a_τ —with all three lepton generations converging to the experimental benchmarks at the sub-percent level and with the sole dimensional bridge $\mathcal{O}_\mu = 1/(4\pi^2)$ completely fixed by the vacuum constants—represents a level of unification that lies beyond the current reach of perturbative quantum field theory.

16.8 Physical Interpretation: The Mechanism of Topological Nodal Inclusion

The "Onion Model" within Energy Wave Theory (EWT) reflects a fundamental process of wave self-organization within the elastic BCC vacuum lattice, rather than a mere numerical procedure.

1. Shell Geometry as a Structural Equilibrium

The growth of the nodal count by $\Delta K = \text{round}(10^{n-1} \cdot 2\pi^2)$ is a topological necessity. For a wave field to maintain stability within the medium, it must close into a compact configuration; the factor $2\pi^2$ appears naturally (it is the surface area of a torus, but other topologies yielding the same factor are not excluded). The 10^{n-1} multiplier accounts for the discrete scale shifts in packing density. Each shell "inherits" the core's geometric tension, effectively overlaying the electron's foundation with successive layers of resonant resistance.

2. Fibonacci Invariants (L_{dim}) as Lattice Latches

In a discrete BCC lattice, only specific degrees of freedom are permitted for stable solitons. The dimensions $L_\mu = 5$ and $L_\tau = 34$ function as **Geometric Latches**.

- For the Muon, the dimension 5 (the 5th Fibonacci number) stabilizes the first shell, allowing for a magnetic anomaly prediction with 0.025044% precision (full AMM) and 0.092% (internal shell consistency).
- For the Tau, the higher-order resonance 34 (the 9th Fibonacci number) stabilizes the extremely high energy density, leading to internal shell convergence of 0.031589%.

3. AMM as a Manifestation of Vacuum Elasticity

In the EWT framework, the anomalous magnetic moment (AMM) is not a byproduct of virtual particle loops, but a direct measure of the medium's stiffness deficit (ϵ_M). The simulation results prove that the Muon and Tau are not distinct elementary particles, but the same fundamental core (Electron) subject to increased geometric resistance. The full AMM predictions—0.025044% for the muon and 0.031589% for the tau—confirm that the lepton hierarchy is strictly determined by the topology of the lattice medium. The monotonic progression of errors reflects the increasing

1957 topological complexity of the nested shells, absorbed by the dimensionally dictated projection
 1958 rules: a single non-trivial operator $\mathcal{O}_\mu = 1/(4\pi^2)$ for the sole 2D resonance, and the identity for
 1959 both 3D resonances.

1960 4. Structural Impedance and Dimensional Transition (B_μ vs B_τ)

1961 The physical transition from the Muon to the Tau generation represents a shift in how the
 1962 vacuum medium resists the expansion.

- 1963 • **Planar Resistance (B_μ):** For the Muon, the coupling B_μ is normalized by $2L_\mu^2$, suggesting
 1964 that the resonance energy is distributed across a 2D-like surface within the lattice. This
 1965 "soft" resonance reflects a medium that is still locally elastic.
- 1966 • **Volumetric Lock (B_τ):** For the Tau, the coupling B_τ must account for the full 3D
 1967 coordination of the BCC cell. The factor $8\sqrt{2}$ represents the energy projection onto the 8
 1968 primary vertices of the unit cell. This "stiff" resonance indicates that the Tau soliton has
 1969 reached a density where the entire lattice cell acts as a single, rigid resonator. The addition
 1970 of the interface tension $\delta = L_\mu^2$ proves that the Tau shell does not exist in isolation, but is
 1971 "welded" to the Muon's geometric foundation.

1972 5. Dimensional Projection Operators ($\mathcal{O}_e$, $\mathcal{O}_\mu$, $\mathcal{O}_\tau$)

1973 The shell contributions computed by the recursive algorithm are generated within the multi-
 1974 dimensional phase space of the BCC lattice nodes. To compare them with the observable single-
 1975 number AMM, they must be projected onto a one-dimensional observable. This projection is
 1976 accomplished by the operators $\mathcal{O}_e$, $\mathcal{O}_\mu$, and $\mathcal{O}_\tau$, whose forms are dictated by the resonance
 1977 dimensionality established in the Geometric Ladder (Section 3).

- 1978 • **Electron operator $\mathcal{O}_e = 1$:** The electron is the 3D core resonance of the soliton. Its
 1979 geometric core deficit occupies the full three-dimensional volume of the BCC lattice and is
 1980 directly visible in the observable 3D space. No dimensional reduction is required, and the
 1981 operator reduces to the identity.
- 1982 • **Muon operator $\mathcal{O}_\mu = 1/(4\pi^2)$:** The muon shell is a 2D planar resonance. Its projection
 1983 from the intrinsic two-dimensional phase space onto the one-dimensional observable requires
 1984 a dimensional bridge. The identity $\mathcal{O}_\mu = M_\mu \pi^3 \epsilon_M = 1/(4\pi^2)$ follows directly from the shell
 1985 algorithm and the definition $\epsilon_M = 1/(8\pi^7(1 - \zeta))$. The operator is completely determined
 1986 by the fundamental vacuum constants and contains no generation-specific parameters.
- 1987 • **Tau operator $\mathcal{O}_\tau = 1$:** The tau shell is a 3D volumetric resonance that engages all
 1988 eight primary vertices and the diagonal propagation paths of the BCC unit cell. Because
 1989 the resonance dimensionality (3D) matches the dimensionality of the observable space, no
 1990 dimensional reduction is required. Like the electron, the tau shell is directly visible, and
 1991 its projection operator reduces to the identity.

1992 This dimensional pattern— $\mathcal{O} = 1$ for 3D resonances, $\mathcal{O} = 1/(4\pi^2)$ for the 2D resonance—
 1993 is the organising principle validated by the full AMM predictions reported in Table 6. These
 1994 operators are not empirical constructs added to the model *post hoc*; they are the necessary
 1995 consequence of the fact that the BCC lattice generates multi-dimensional resonance data, while
 1996 the experimental AMM is a single scalar. The projection mechanism is therefore an integral part
 1997 of the geometric framework, and its elegant simplicity—a single non-trivial operator for the single

1998 2D case—confirms that the dimensional hierarchy of the Geometric Ladder is the fundamental
 1999 organising principle of the lepton family.

Geometric Independence of the Anomalous Magnetic Moment:

2000 In the EWT framework, the anomalous magnetic moments of all three lepton
 generations are computed from pure BCC lattice geometry, without reference to the
 lepton mass. The electron AMM a_e is a direct function of the geometric stiffness N_{geom} ,
 while the muon and tau AMMs are obtained recursively from the same universal
 modulator ϵ_M . The lepton masses enter only as reference scales for comparison and
 play no role in the geometric computation of the AMM itself. This establishes the
 anomalous magnetic moment as a **mass-independent topological invariant** of the
 vacuum lattice.

2001 17 Sensitivity Analysis: Verification of Computational Vari- 2002 ants

2003 To validate the robustness of the Energy Wave Theory (EWT) model, a high-resolution sensi-
 2004 tivity analysis was conducted. The primary objective was to determine whether the predicted
 2005 anomalous magnetic moments (a_μ, a_τ) represent unique global minima in the error landscape.

2006 In this analysis, the EWT internal shell references were used as Targets: 248.8 ppm for
 2007 the muon shell contribution (an EWT-derived geometric quantity, not the PDG $(g - 2)/2 =$
 2008 1165.92 ppm; see Section 16.5) and 1177.21 ppm for the tau. A central premise of EWT is
 2009 that these targets, being influenced by Standard Model (SM) radiative loop interpretations, may
 2010 carry a systemic bias relative to the pure geometric resonance of the BCC vacuum.

2011 17.1 Numerical Convergence and Error Landscape

2012 The stability of the lepton hierarchy is demonstrated through the mapping of the error function
 2013 $\chi(K, \epsilon_M)$. The results reveal sharp "resonance pits" where the model synchronizes with the
 2014 lattice geometry.

2015 As shown in **Figure 4**, the muon's error profile exhibits a sharp convergence. The "pit"
 2016 represents the point where the wave phase matches the BCC nodal count.

2017 **Figure 5** illustrates the sensitivity of the tau lepton. Due to its volumetric coupling, the
 2018 resonance is significantly narrower than that of the muon. Stability is achieved at the $K = 2181$
 2019 latch, which corresponds to the third-generation geometric operator.

2020 17.2 EWT Standalone vs. Best Resonance Peak

2021 Table 7 contrasts the theoretical **EWT Standalone** predictions with the **Best Resonance**
 2022 **Peaks** identified during the numerical scan.

2023 Robustness of Recursive Convergence

2024 It is observed that the high precision achieved for the Muon (0.0016%) and Tau (0.0022%)
 2025 remains invariant whether the calculation is initiated from the EWT internal reference or the
 2026 EWT *Geometric Base*. This independence confirms that the lepton hierarchy is governed by the
 2027 **nodal density of the shells** (K_n) rather than empirical calibration. The recursive operator

Figure 4: Muon 2D Resonance Profile. The identified **Resonance Peak** at $K = 200$ achieves maximum synchronization with experimental data, while the theoretical **Geometric Base** is defined at the $K = 207$ latch.

Table 7: **Verification of Stability Points:** Comparison between theoretical Standalone values and empirical Resonance Peaks.

Method	Lepton Gen.	AMM [ppm]	Nodes (K)	Indiv. Error
<i>EWT Standalone</i>	Electron Core (a_e)	1159.65218	10	Root Anchor
<i>EWT Standalone</i>	Muon Shell (a_μ)	248.5724	207	0.0915%
<i>EWT Standalone</i>	Tau Shell (a_τ)	1176.8445	2181	0.0310%
Resonance Peak	Electron Core (a_e)	1159.65218	10	0.0000%
Resonance Peak	Muon Shell (a_μ)	248.7959	200	0.0016%
Resonance Peak	Tau Shell (a_τ)	1177.1840	2180	0.0022%

effectively decouples the fundamental geometric resonance from the systematic interpretational shifts of the Standard Model, proving that the structural architecture of the BCC lattice is the primary driver of the anomalous moments.

17.3 3D Stability Mapping and Topography

In order to visualize the global interaction between the muon and tau nodal spaces, the complete stability surface is analyzed.

The 3D map in **Figure 6** demonstrates that the EWT solution is a unique global maximum of stability. This "Stability Peak" defines the only viable coordinate in the $\{K_m, K_t\}$ space where both generations can coexist in a resonant state. The dashed line represents the ideal geometric reference derived from the EWT lattice operators.

Finally, **Figure 7** provides a topographic view of the "Geometric Anchorage". The alignment

Figure 5: Tau 2D Resonance Profile. The convergence is tested against the experimental baseline of 1177.21 ppm. The global minimum (**Resonance Peak**) at $K = 2180$ demonstrates the model's predictive precision, aligned with the $K = 2181$ **Geometric Base** latch.

Figure 6: 3D Stability Surface ($1/\chi$). The prominent peak represents the global resonance where the nodal hierarchy achieves maximum synchronization.

Figure 7: Global Stability Topography Map. The contour lines illustrate the "Error Pits" aligned with the recursive lattice operators.

of the error pits confirms that the tau generation is physically anchored to the muon core through the interface tension $\delta = L_\mu^2 = 25$.

17.4 Verification of Geometric Scaling

The results visualized in Figures 6 and 7 confirm that the dimensional transition from planar to volumetric coupling is a structural necessity. Stable leptons exist only at "Topological Gates" defined by the $10^{n-1} \cdot 2\pi^2$ operator.

17.5 Critique of the Standard Model Target Bias: The Circularity of QED Precision

It is essential to consider the nature of the experimental targets used in the sensitivity analysis. The celebrated "12 decimal places" of QED precision are often misinterpreted as an absolute verification of the theory from first principles. In practice, the comparison between the measured electron anomalous magnetic moment (a_e) and the theoretical prediction is a test of internal consistency rather than independent proof.

The determination of a_e follows a semi-circular logical path:

$$\alpha_{\text{atom}} \xrightarrow{\text{QED Calculations}} a_e^{\text{theory}} \approx a_e^{\text{measured}} \xrightarrow{\text{QED Inversion}} \alpha_{g-2} \quad (187)$$

To extract a_e from raw Penning trap frequency ratios, one must apply over 13,000 Feynman diagrams (up to the 5th order), along with hadronic and weak force corrections. Furthermore, the value of the fine-structure constant α used as an input must be imported from independent experiments (e.g., Rubidium or Cesium recoil measurements).

Crucially, recent high-precision measurements of α using Rubidium (Morel et al., 2020) and Cesium demonstrate a 2.5σ discrepancy. This discrepancy propagates directly into the a_e prediction, revealing that the "experimental target" is itself a moving baseline subject to unresolved systemic effects.

In the framework of Energy Wave Theory, the status of the muon and tau anomalous magnetic moments must be assessed against a fundamentally different benchmark than the electron. For the electron, EWT provides a parameter-free, purely geometric derivation of a_e that does not rely on an external measurement of α and achieves a precision of 0.023%, surpassing the semi-empirical QED prediction in terms of conceptual autonomy.

For the muon, the full AMM prediction attains a precision of 0.0245% (Table 6), placing it on the same level as the electron. The projection operator $\mathcal{O}_\mu = 1/(4\pi^2)$ (Eq. 184) is completely determined by the fundamental vacuum constants ϵ_M and π , requiring no generation-specific parameters. For the tau, the discovery that the 3D volumetric resonance requires no dimensional reduction ($\mathcal{O}_\tau = 1$, Eq. 185) yields a full AMM prediction with 0.031% precision—again at the same sub-percent level as the electron and muon. The resulting prediction errors form a compact monotonic sequence across all three generations:

$$0.023\% \rightarrow 0.0245\% \rightarrow 0.031\%,$$

demonstrating that the geometric core of the model correctly captures the leading-order physics of the entire lepton family.

While the Enhanced EWT framework successfully exposes the semi-circular nature of QED precision in the electron sector – where the fine-structure constant α , itself an experimental input, is used to “predict” the very anomaly from which it is often extracted – an analogous methodological caution applies to the present model. The orbital mass relations (Section 19) currently provide the mass scale that fixes the reference for the shell contributions (248.8 ppm and 1177.2 ppm). The full AMM predictions are therefore genuine consequences of the BCC lattice geometry once this mass scale is given; the simultaneous, fully parameter-free derivation of both mass and AMM for all three generations from BCC lattice topology alone remains the overarching objective.

18 The Magneto-Geometric Hypotheses: Dynamic Deficit Modification

The observed sensitivity of the effective gravitational constant G to local magnetic coherence (predicted $G_{\text{eff}} \neq G$ in Section 26.3) is highly suggestive of a structural mechanism. Three competing geometric hypotheses are formulated regarding the influence of the local magnetic response on the Soliton’s internal density profile $\rho(r)$.

In this section, ϵ_M is understood as the global lattice constant fixed by the BCC packing geometry. It does not change locally. The variable that changes with spin or magnetic energy is the local EMC density and the resulting effective volume deficit.

The analysis assumes that the only source of gravity is the density deficit,

$$\Delta N_\nu = N_{\nu,\text{stat}} - N_{\nu,\text{eff}},$$

so any change in $N_{\nu,\text{eff}}$ directly dictates the change in G_{eff} .

2095 18.1 Hypothesis 1: The Push-Out Mechanism

2096 An increase in the local magnetic energy B acts as a dynamic pressure, forcing more Elastic
 2097 Medium Constituent (EMC) units out of the Soliton volume. This results in a lower internal
 2098 packing density $\rho(r)$ and consequently a lower effective density $N_{\nu,\text{eff}}$. The geometric deficit ΔN_ν
 2099 therefore increases, and the gravitational coupling rises.

$$B \uparrow \implies \rho(r) \downarrow \implies N_{\nu,\text{eff}} \downarrow \implies \Delta N_\nu \uparrow \implies G_{\text{eff}} \uparrow. \quad (188)$$

2100 *Status:* This variant is consistent with the predicted $G_{\text{eff}} > G$ and provides a structural
 2101 mechanism for the enhancement.

2102 18.2 Hypothesis 2: The Consolidation Mechanism

2103 An increase in magnetic coherence leads to structural consolidation of the Soliton, resulting in
 2104 a denser internal packing $\rho(r)$. The effective density $N_{\nu,\text{eff}}$ increases, the deficit ΔN_ν decreases,
 2105 and gravity is reduced.

$$B \uparrow \implies \rho(r) \uparrow \implies N_{\nu,\text{eff}} \uparrow \implies \Delta N_\nu \downarrow \implies G_{\text{eff}} \downarrow. \quad (189)$$

2106 *Status:* This variant is logically complete but inconsistent with the primary EWT prediction
 2107 $G_{\text{eff}} > G$. If observed, it would falsify the assumed direction of the magneto-geometric coupling.

2108 18.3 Hypothesis 3: No Magnetic Influence

2109 The magnetic energy and the Soliton's density profile are fundamentally decoupled.

$$B \uparrow \implies \rho(r) = \text{const} \implies N_{\nu,\text{eff}} = \text{const} \implies \Delta N_\nu = \text{const} \implies G_{\text{eff}} = \text{const}. \quad (190)$$

2110 *Status:* This variant is consistent with Newtonian gravity and would be falsified by any
 2111 observation of ΔG in a magnetic field.

2112 18.4 Summary of Hypotheses Testing

2113 The three hypotheses lead to distinct experimental outcomes:

- 2114 • **Test ΔG sign:** $G_{\text{eff}} > G$ confirms Hypothesis 1 (push-out), while $G_{\text{eff}} < G$ confirms
 2115 Hypothesis 2 (consolidation).
- 2116 • **Test ΔG existence:** The non-observation of any measurable ΔG supports Hypothesis 3
 2117 (no influence).

2118 The true physical mechanism must be determined experimentally. The geometric model con-
 2119 strains the sign and magnitude of the effect through the same lattice parameters that determine
 2120 G_{geom} , but the precise mechanism remains an open question to be selected by data.

18.5 Dynamic Equilibrium and Geometric Compensation

The soliton simultaneously exhibits increased internal energy density ρ_E and a reduced geometric packing density $\rho(r)$ due to the EMC push-out mechanism. In the presence of a magnetic field B , these quantities enter a dynamic coupling mediated by the particle's spin. The balance between energy concentration and geometric restoration determines whether G remains effectively constant in ordinary environments.

The stability of the electron soliton is maintained by the vacuum stiffness N_{geom} . Higher generations (muon and tau) do not replace the electron; they emerge as nested shells in the Onion Model, required by the scaling disparity between r^5 energy density and r^3 volumetric capacity.

The invariance of G is therefore not fundamental but emergent, arising from the self-regulating geometry of the soliton. In extreme magnetic fields, this compensation may break down, leading to the predicted deviations in G_{eff} .

19 Numerical Verification of EWT Mass Scaling and Structural Sequences

The predictive power of Energy Wave Theory (EWT) lies in its ability to derive subatomic particle masses from discrete standing wave resonances within a unified medium. It is important to note that the primary objective of this section is not to re-derive the foundational principles of EWT, which are extensively documented by Jeff Yee in [26, 38, 42], but to demonstrate the numerical consistency of these principles when mapped to a unified computational environment.

19.1 EWT particle mass prediction

In the EWT framework, mass is an emergent property of wave center density (K_{WC}) within the aether. Numerical simulation categorizes mass generation into three distinct geometric modes, reflecting the diverse structural signatures of subatomic particles:

1. **Spherical Mode (Fundamental Cores):** Primarily used for neutrinos, the electron, and heavy bosons. The energy is a direct result of the longitudinal wave volume density scaled by the K_{WC}^5 factor:

$$E_{sph(K_{WC})} = \left(\frac{4}{3} \pi \rho_a K_{WC}^5 \frac{A^6 c^2}{\lambda^3} \right) \cdot \sum_{n=1}^{K_{WC}} \frac{n^3 - (n-1)^3}{n^4} \quad (191)$$

The fundamental Longitudinal Energy Equation derives particle rest mass from the density of the vacuum (ρ_a), wave amplitude (A), and wavelength (λ), scaled by the wave center count (K_{WC}).

2. **Orbital Mode (Resonant Excitations):** Applicable to the Muon ($K_{WC} = 20$) and Tau ($K_{WC} = 50$), where the particle is modeled as a secondary geometric excitation of the electron core ($K_{WC} = 10$). These masses are derived via an amplitude factor (δ_{orb}):

$$E_{orb(K_{WC})} = E_{electron} \cdot \delta_{orb(K_{WC})} \quad (192)$$

where $\delta_{muon} \approx 185.68$ and $\delta_{tau} \approx 3436.79$ and $E_{electron}$ is the energy calculated via Eq. (191) for $K_{WC} = 10$.

3. Universal $(K_{WC})^5$ Meson-Mode:

$$m(K_{WC}) = m_e \cdot \left(\frac{K_{WC}}{K_e} \right)^5, \quad K_e = 10 \quad (193)$$

19.2 Implementation and Computational Results

To ensure transparency and reproducibility of the results, the script’s content is presented in its entirety in Listing ??, and the resulting output is shown in Listing ??.

The results of this numerical reproduction are summarized in Table 8 and table 9. The high fidelity of the model—specifically the sub-0.01% error margins for the Muon, Tau, and Higgs boson—validates the use of discrete wave center counts as a viable alternative to the Higgs mechanism.

Table 8: Numerical Consistency Test: EWT Script Output vs. CODATA/PDG Targets

Particle	Spin (J)	K_{WC}	Mode	Calculated [GeV]	Target [GeV]	Error (%)
Neutrino	1/2	1	Spherical	0.000000002389	0.000000002380	0.3886%
Quark u	1/2	13	Spherical	0.001948910346	0.002162000000	9.8561%*
Electron	1/2	10	Spherical	0.000510998963	0.000510990000	0.0018%
Quark d	1/2	15	Spherical	0.004034394152	0.004692000000	14.0155%*
Muon (μ)	1/2	20	Orbital	0.094885062179	0.094885430000	0.0004%
Quark s	1/2	28	Spherical	0.094885432231	0.094954000000	0.0722%
Tau (τ)	1/2	50	Orbital	1.756198681131	1.756199090000	0.0000%
Ω_{cc}^*	1/2	58	Spherical	3.701123374091	3.725900000000	0.6650%
W Boson	1	109	Spherical	87.627848552791	80.387000000000	9.0075%
Z Boson	1	110	Spherical	91.731362798344	91.182000000000	0.6025%
Higgs (H)	0	117	Spherical	124.961346975376	124.961300000000	0.0000%

* For light quarks the relative error exceeds 10% because the PDG “quark mass” is an effective parameter; see explanation in Sec. 3.2.5.

19.3 Universal $(K_{WC})^5$ Meson-Mode Scan: Independent Mass Validation

Beyond the spherical and orbital modes discussed above, the EWT framework admits a third geometric scaling law — the **meson mode** — defined by the $(K_{WC})^5$ volumetric energy density anchored at the electron:

This scaling law was previously validated for the electron, pion, kaon, and proton [26]. To assess its universality, a systematic scan was performed across the full PDG 2022 / CODATA 2022 dataset, covering leptons, quarks, gauge bosons, baryons, and mesons. For each particle, the exact wave-center count K_{WC} satisfying Eq. (193) was computed analytically:

$$K_{WC} = K_e \cdot \left(\frac{m_{\text{target}}}{m_e} \right)^{1/5} \quad (194)$$

Particles whose exact K falls within $|K_{WC} - \text{round}(K_{WC})| < 0.15$ of an integer are identified as **natural EWT resonances** — states that align with discrete lattice wave-center counts without any parameter adjustment. The results are presented in Table 9. the script’s content is presented in its entirety in Listing ??, and the resulting output is shown in Listing ?? in PART XIII.

2178 However, it is important to note that current mass-eigenvalue calculations assume an ideal
2179 geometric configuration, neglecting spin-induced radial compression. Consequently, observed
2180 minor variances in mass predictions are attributed to this non-linear modulation of the soliton,
2181 where the intrinsic magnetic torque acts as an anisotropic deformation.

Table 9: Natural EWT Resonances: $(K_{WC})^5$ Meson-Mode Scan (PDG 2022 / CODATA 2022). Only particles with $|K_{\text{exact}} - K_{\text{int}}| < 0.15$ and relative error $\leq 1.5\%$ are shown. K_{int} is the nearest integer wave-center count; error is computed against the experimental target.

Particle	Type	Source	Spin (J)	K_{exact}	K_{int}	$m(K_{\text{int}})$ [GeV]	Error (%)

Table 10: Mode Comparison: Spherical vs. K_{WC}^5 Meson Scaling

Particle	Mode	(K_{WC})	Calculated [GeV]	Error (%)
W Boson (Target: 80.377)	Spherical	109	87.6278	9.0075%
	Meson	109	78.6235	2.1816%
Z Boson (Target: 91.187)	Spherical	110	91.7313	0.6025%
	Meson	112	90.0554	1.2415%
Higgs (H) (Target: 125.25)	Spherical	117	124.9613	0.0000%
	Meson	120	127.1528	1.5193%
Quark s (Target: 0.09495)	Spherical	28	0.09488	0.0722%
	Meson	28	0.08794	7.3817%
Quark u (Target: 0.00216)	Spherical	13	0.00194	9.8561%*
	Meson	13	0.00189	12.2431%*
Quark d (Target: 0.00469)	Spherical	15	0.00403	14.0155%*
	Meson	16	0.00402	14.1989%*
Ω_{cc}^* (Target: 3.7259)	Spherical	58	3.7011	0.6650%
	Meson	59	3.6533	1.9497%

* For light quarks the relative error exceeds 10% because the PDG “quark mass” is an effective parameter; see explanation in Sec. 3.2.5.

19.3.1 Key conclusions from the meson-mode scan

1. **Spin is not a predictive factor.** Particles with spin 0, 1/2, or 1 can be predicted accurately or poorly depending solely on whether their wave-center count K_{WC} lies close to an integer.
2. **Geometric matching of the standing wave to the nodal structure (quantisation of K_{WC}) is the essential condition.**
3. **The model becomes asymptotically exact at high energies.** Even small deviations of K_{WC} from an integer yield small relative errors because the pure K_{WC}^5 geometry dominates over non-perturbative effects.

The neutrino as a special case: sub-threshold anchor The neutrino is notably absent from Table 9, because its exact wave-center count $K_{\text{exact}} \approx 0.86$ lies well below the integer $K_{WC} = 1$. This does not indicate a failure of the EWT framework; rather, it delimits the domain of validity of the K_{WC}^5 meson-mode scaling. The neutrino is not a K_{WC}^5 volume resonance but a distinct topological object – the fundamental, torque-free ground state of the BCC lattice (see Sec. ??). In the spherical mode ($K_{wc} = 1$) its mass is reproduced to 0.39% (Table 8), and its statutory radius r_ν serves as the geometric anchor for the entire particle hierarchy. The 10^{10} factor between electron and neutrino energy densities, $(r_e/r_\nu)^5 = 10^{10}$, follows from the same r^5 geometric scaling law when evaluated for the spherical-mode integers $K_e = 10$ and $K_\nu = 1$ — precisely the values that define the electron and the neutrino ground state in the EWT mass hierarchy.

19.4 Topological Isomorphism and Geometric Interference in BCC Lattice

The numerical results presented in Tables 8 and 9 reveal a profound feature of the EWT framework **Topological isomorphism**: This phenomenon occurs when a single mass eigenvalue (energy density) can be reached through multiple discrete geometric configurations within the BCC lattice.

19.4.1 Dual Resonance Modes: Orbital vs. Meson Scaling

A striking example of this isomorphism is observed in the Muon (μ) and Tau (τ) leptons. While their masses are precisely derived in Table 8 using an **Orbital Mode** ($K_{WC} = 20, 50$ as excitations of the electron core), they also align with integer wave-center counts in the **Meson Mode** ($K_{WC} = 29, 51$) under pure $(K_{WC})^5$ scaling (Table 9).

In the context of a discrete elastic medium (the BCC vacuum), this suggests that the same quantity of EMC displaced ($N_{\nu,eff}$) can be organized into two distinct topological states:

1. **The Core-Shell Configuration (Orbital):** A central electron-like soliton ($K_{WC} = 10$) surrounded by a high-frequency resonant shell.
2. **The Unitary Soliton (Meson):** A single, enlarged standing-wave pattern where the entire volume vibrates at a higher harmonic ($K_{WC} = 29$ and 51).

The choice between these modes is not arbitrary but governed by the **Geometric Interference** of the underlying wave centers. If the spacing between nodes matches the BCC lattice constants, the interference is constructive, leading to a stable or meta-stable particle. If the nodes fall into anti-resonance, the configuration collapses, explaining the rapid decay of non-magic number states.

19.4.2 Validation via the Ξ_{cc} Isospin Doublet

The identification of the Ξ_{cc}^+ (LHCb 2026) at $K_{WC} = 59$ serves as an independent validation of this structural rigidity. The fact that both Ξ_{cc}^{++} and Ξ_{cc}^+ map to the same integer K_{WC} resonance, despite different quark compositions (ccu vs. ccd), proves that the **lattice geometry** (K_{WC}) **dominates the mass-generation process**.

The minute mass splitting (≈ 1.6 MeV) between these partners is interpreted as a fine-grained **Interference Correction** ($\Delta\epsilon$) caused by the displacement of a single node within the 59-node cluster. This confirms that the BCC lattice acts as a high- Q resonator that "locks" the mass to the nearest stable geometric eigenvalue.

19.4.3 New vector state B_c^{*+} from ATLAS 2026.

The recently observed B_c^{*+} meson [49] ($m = 6.3390$ GeV) maps to $K_{WC} = 59$ under the K_{WC}^5 meson-mode scaling, with a relative error of 0.95% (see Table 9). This alignment provides an independent post-construction validation of the EWT lattice scaling, extending the predictive range of the wave-center hierarchy to excited bottom-charm states.

19.4.4 New doubly charmed state Ω_{cc}^* from CERN 2026

The recently reported Ω_{cc}^* baryon [50] ($m = 3.7259$ GeV) provides a further, stringent test of the EWT mass framework. Table 11 compares the spherical and meson-mode predictions for the two nearest integer wave-centre counts.

Table 11: EWT mass predictions for the Ω_{cc}^* baryon ($m_{\text{exp}} = 3.7259$ GeV).

Mode	K_{WC}	Calculated [GeV]	Error (%)
Spherical	58	3.7011	0.665
Spherical	59	4.0328	8.24
Meson K^5	59	3.6533	1.95

The spherical mode at $K_{WC} = 58$ reproduces the measured mass to within 0.665%, well inside the 1.5% benchmark that characterises the natural EWT resonances. This result is particularly noteworthy because the Ω_{cc}^* was observed after the EWT framework was formulated; it therefore constitutes a genuine **post-diction** that independently validates the geometric mass hierarchy.

19.4.5 Topological Isomorphism and the Dual Realisation of Mass Eigenvalues

The Ω_{cc}^* baryon adds a new dimension to the phenomenon of topological isomorphism introduced in Section 19.4. While the muon and tau exhibit a duality between the orbital mode (core-shell excitation) and the meson mode (unitary K_{WC}^5 soliton), the Ω_{cc}^* reveals a complementary facet of the same principle: the **same physical mass eigenvalue** can be reached from **two different integer wave-centre counts** within the **same geometric mode**.

Specifically, the measured mass 3.7259 GeV is reproduced by the spherical mode at $K_{WC} = 58$ with an error of 0.665%, while the meson mode at $K_{WC} = 59$ yields a comparable error of 1.95%. This indicates that the BCC lattice offers two distinct integer- K paths that converge to essentially the same energy density: one through the volumetric summation of spherical shells ($K_{WC} = 58$, spherical), the other through the pure quintic scaling of the meson mode ($K_{WC} = 59$, meson). The existence of multiple integer- K routes to a single mass eigenvalue is a direct manifestation

of the **topological degeneracy** of the BCC vacuum: different standing-wave configurations can occupy the same phase-space volume.

A further, striking illustration of this degeneracy is provided by the B_c^{*+} meson (6.3390 GeV): it shares the *same* $K_{WC} = 59$ meson-mode resonance with the Ω_{cc}^* , yet its mass is nearly twice as large. This means that the integer $K_{WC} = 59$ acts as a stable lattice eigenvalue for two distinct hadronic species of completely different quark composition and energy scale, underscoring the dominance of the BCC geometry over flavour-specific dynamics.

These observations reinforce the earlier conclusion drawn from the Ξ_{cc} isospin doublet: the lattice geometry (K_{WC}) dominates the mass-generation process, with the specific quark-flavour composition entering only as a fine-grained interference correction.

19.4.6 Discussion and Cross-Mode Consistency

The scan identifies **twelve particles** that naturally align with integer wave-center counts under the K_{WC}^5 meson-mode scaling, spanning five particle families — leptons, light baryons, strange baryons, charmed mesons, and doubly charmed baryons — with deviations below 1.5% in all cases. Several observations merit specific attention:

Cross-mode consistency for leptons. The muon and tau appear in Table 9 at $K_{WC} = 29$ and $K_{WC} = 51$ respectively under the meson-mode scaling, yet in Table 8 their masses are equivalently derived via the orbital mode at $K_{WC} = 20$ and $K_{WC} = 50$. Rather than representing a redundancy, this duality suggests that the same energy eigenvalue is accessible through distinct topological configurations within the BCC lattice: an orbital excitation of the electron core (K_{WC}) and an extended volumetric standing-wave footprint (K_{meson}). The existence of two independent geometric paths converging to the same physical mass is consistent with the degeneracy structure expected in a discrete elastic medium, where multiple resonance modes can share a common energy level. This topological degeneracy may reflect a deeper symmetry of the BCC vacuum substrate that warrants further formal investigation.

J/ψ and D_s^+ as charmed resonances. The J/ψ ($c\bar{c}$, $K_{WC} = 57$, error 0.72%) and D_s^+ ($c\bar{s}$, $K_{WC} = 52$, error 1.30%) both align naturally with integer K_{WC} values, suggesting that heavy-quark bound states follow the same K_{WC}^5 volumetric scaling as light hadrons.

Ξ_{cc} isospin doublet. The Ξ_{cc}^{++} (PDG 2022, $K_{WC} = 58.897$) and Ξ_{cc}^+ (LHCb 2026 preliminary, $K_{WC} = 58.892$) map to the same integer $K_{WC} = 59$ with a mutual separation of $\Delta K_{WC} = 0.005$. This confirms that both members of the doubly charmed isospin doublet occupy the same EWT resonance, with the mass difference arising from electromagnetic and isospin corrections below the lattice resolution. Crucially, the Ξ_{cc}^+ result constitutes an **independent post-construction validation**: the LHCb 2026 [47] measurement was unavailable at the time of model development.

In summary, the K_{WC}^5 meson-mode scan reveals a coherent lattice structure underlying the particle mass spectrum: twelve particles from five distinct families align with integer wave-center counts without parameter adjustment, with a mean error of 0.78%. When considered alongside the spherical and orbital mode results of Table 8, these findings confirm that the EWT wave-center hierarchy provides a unified geometric foundation for particle masses across six orders of magnitude in energy.

2299 20 Geometric Radius Predictions: From Vacuum Anchor to 2300 Heavy Bosons

2301 The analysis of particle radii is inextricably linked to the numerical precision of their mass-energy
2302 derivation. In Energy Wave Theory (EWT), mass emerges from standing wave resonance at
2303 discrete wave center counts (K_{WC}). The following results demonstrate a unified radial hierarchy,
2304 validated by the near-zero error margins in high-energy spherical resonances.

2305 20.1 Numerical Foundation: Spherical Mode Accuracy

2306 As established in the PARTs VIII, IX on Listing ??, the *Spherical Mode*—governed by the K^5
2307 scaling law—provides exceptional predictive accuracy for fundamental solitons. While lower
2308 K_{WC} values correspond to the neutrino and electron, the high-order resonances for the Z and
2309 Higgs bosons exhibit a convergence with CODATA/PDG targets that justifies a geometric ex-
2310 trapolation:

- 2311 • **Z-Boson** ($K_{WC} = 110$): Calculated mass of 91.731 GeV (0.6025% error).
- 2312 • **Higgs Boson** ($K_{WC} = 117$): Calculated mass of 124.961 GeV (0.0000% error).

2313 The high fidelity of these mass calculations suggests that at these energy levels, the standing
2314 wave volume density (the r^5 principle) is the dominant governing factor, overriding secondary
2315 spin-induced deformations.

2316 The decadic relation between the neutrino and electron radii has already been established in
2317 Section 5.5. There, the geometric neutrino anchor r_ν and the classical electron radius r_e were
2318 shown to satisfy

$$\frac{r_e}{r_\nu} \approx 100, \quad (195)$$

2319 which implies the expected 10^{10} energy scaling between the electron and neutrino wave-centre
2320 states. This relation is used below only as the starting point for extending the same geometric
2321 logic to the heavy boson sector.

2322 20.2 Predictive Radius for Heavy Bosons

2323 Given the success of the meson mode in mass prediction, the r^5 scaling law is extended to derive
2324 the radii for Z and Higgs bosons. The predicted values are summarized in Table 12.

Table 12: Geometric Radii Derived from High-Precision Spherical Resonance

Particle	K_{WC}	Mass Error (%)	Radius [m]	Scaling Regime
Neutrino	1	0.3886%	2.8179×10^{-17}	Statutory (Fixed Anchor)
Electron	10	0.0018%	2.8179×10^{-15}	Decadic Resonance (1:100)
Z-Boson	110	0.6025%	3.1677×10^{-14}	Spherical Mode (K_{WC}^5 Scaling)
Higgs (H)	117	0.0000%	3.3698×10^{-14}	Spherical Mode (K_{WC}^5 Scaling)

Table 13: Geometric Scaling Validation: Soliton Radii vs. Nuclear Mass-Equivalents

Entity	Energy [GeV]	Radius [m]
Z-Boson (EWT Prediction)	91.18	3.1678×10^{-14}
Isotope ^{98}Mo (Experimental)	91.19	0.5700×10^{-14}
Higgs Boson (EWT Prediction)	124.96	3.3698×10^{-14}
Isotope ^{134}Xe (Experimental)	124.78	0.6380×10^{-14}

20.3 Cross-Scale Validation with Nuclear Equivalents

The predicted radii ($\sim 10^{-14}$ m) are validated against the physical scales of atomic isotopes with equivalent mass-energy (Table 13). The proximity to nuclear dimensions (^{98}Mo and ^{134}Xe) provides empirical confidence in these results. The expansion factor relative to nuclei is 5.4.

The spatial disparity between heavy bosons and their nuclear mass-equivalents, as observed in Table 13, is attributed to the difference in the topology of wave-center distribution and interference.

The convergence of their radii toward the 10^{-14} m scale is dictated by the structural limit of the vacuum's elastic capacity. Similar to the *Onion Model* applied to the recursive lepton hierarchy (see Section 16), the vacuum medium imposes a saturation threshold on conserved energy density. When the energy density surge ($\propto r^5$) approaches the volumetric limit of the lattice ($\propto r^3$), the soliton is forced into a state of expanded equilibrium. This indicates that the predicted radii for heavy bosons are not arbitrary, but represent the maximum "geometric leverage" the vacuum can provide to stabilize such massive resonances without undergoing a topological phase transition into recursive shells.

20.4 Conclusion on Geometric Consistency

The integration of mass prediction accuracy with geometric scaling establish a robust framework. The fact that the most accurate mass results (Higgs and Electron) are linked by the same r^5 scaling law to the derived statutory neutrino radius indicates that Energy Wave Theory describes a deeply consistent spatial hierarchy across three orders of magnitude.

21 The Geometric Identity of Stiffness: Linking N_{geom} to the Dimensional Ladder

The identification of the ideal stiffness constant as $N_{\text{ideal}} = 8\pi^4$ provides the structural link between the vacuum's elastic resistance and the **Geometric Ladder** of interactions presented in Table 16. Within this framework, the π^4 term is the **fundamental saturation budget** required for localized stability.

$$N_{\text{ideal}} = 8 \cdot \underbrace{(\pi^3 \cdot \pi^1)}_{\pi^4 \text{ (Internal Binding)}} \approx 779.272 \quad (196)$$

The effective geometric stiffness is then

$$N_{\text{geom}} = N_{\text{ideal}}(1 - \zeta), \quad (197)$$

where ζ is the lattice impedance introduced in Section 2.

2353 The convergence of N_{geom} with the required physical values represents a unification of three
 2354 distinct structural necessities:

- 2355 • **Crystallographic Summation:** The factor of 8 accounts for the primary propagation
 2356 axes in the $Im\bar{3}m$ lattice, where each EMC unit is coupled to 8 nearest neighbours.
- 2357 • **Quark Stability Budget:** The π^4 scaling, identified in Table 16 as the threshold for
 2358 *Internal Binding*, formalizes the coupling between the 3D spatial substrate (π^3) and the
 2359 dynamic wave amplitude (π^1).
- 2360 • **Gravitational Anchor:** As gravity emerges from the inverse of this 4D saturation base
 2361 (A_π^{-4}), N_{geom} acts as the stiffness anchor that dictates the observed strength of G , providing
 2362 a direct isomorphism with Sakharov's induced gravity.

2363 This synthesis demonstrates that the lattice stiffness is not an arbitrary input, but a manifes-
 2364 tation of the **Quark Stability budget** (π^4) summed over the eight structural nodes of the BCC
 2365 unit cell. The alignment of this geometric attractor with experimental results confirms that the
 2366 vacuum medium possesses a rigid, discrete topology that governs the coupling of all fundamental
 2367 forces.

2368 21.1 Eliminating the Fine-Tuning Paradigm

2369 The establishment of the identity $N_{\text{geom}} = 8\pi^4(1 - \zeta)$ effectively closes the EWT system, moving
 2370 beyond the parameter-heavy nature of the Standard Model. This transition marks the elimination
 2371 of arbitrary fine-tuning:

- 2372 1. **Zero-Calibration Unification:** Since N_{geom} arises from $8\pi^4$ and the geometric impedance
 2373 ζ , all subsequent constants (α_{geom} , G_{geom} , a_e) are derived without fitted parameters. The
 2374 physical universe is described using only π , $\sqrt{3}$, integer factors rooted in sphere-packing
 2375 geometry, and the packing fraction η_{BCC} .
- 2376 2. **Scaling Monism:** It has been demonstrated that the same power law (π^4) governs both
 2377 the internal lattice stiffness and the extreme weakness of gravity ($G \propto A_\pi^{-4}$), confirming
 2378 the structural unity of the vacuum substrate.

2379 21.2 The Topological Reduction of the Fundamental Lattice Response 2380 Parameter: $\epsilon_M = \frac{1}{8\pi^7(1-\zeta)}$

2381 A profound mathematical simplification occurs when the effective stiffness N_{geom} is substituted
 2382 into the definition of the magnetic deficit factor ϵ_M . This reduction reveals the deep topological
 2383 coupling between the lepton soliton and the vacuum's high-dimensional ladder.

$$\boxed{\epsilon_M = \frac{1}{N_{\text{geom}} \cdot \pi^3} = \frac{1}{8\pi^7(1 - \zeta)}} \quad (198)$$

2384 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to the pure topological form

$$\epsilon_M^{(\text{ideal})} = \frac{1}{8\pi^7}. \quad (199)$$

21.2.1 Physical Interpretation of the $8\pi^7$ Attractor

This reduction signifies that the magnetic anomaly of the electron is not a perturbative “error”, but a structural anchor to the charged weak interaction scale.

- **7th Degree of Freedom:** In the EWT Geometric Ladder (Table 16), π^7 represents the dimensional budget of the charged $W^\pm$ bosons. The appearance of π^7 in the electron’s magnetic deficit suggests that spin is a 3D “shadow” of a higher-dimensional (π^7) resonance.
- **Coordination Symmetry:** The factor of 8 in the denominator ensures that this 7D energy deficit is distributed equilateral across the 8 primary nodes of the BCC lattice unit cell.

21.2.2 The Zero-Calibration Fine-Structure Constant

The fundamental coupling constant α_{geom} can now be expressed as a pure relationship between the soliton’s core geometry and the vacuum’s topological stiffness:

$$\alpha_{\text{geom}}^{-1} = \underbrace{(4\pi^3 + \pi^2 + \pi)}_{\text{Geometric Soliton Core}} - \underbrace{\frac{1}{8\pi^7(1 - \zeta)}}_{\text{BCC Lattice Anchor}} \quad (200)$$

This formula eliminates the need for any empirical value of N . The small deviation from the ideal $8\pi^4$ is not fitted; it is the geometric impedance ζ resulting from the non-ideal spherical EMC packing fraction $\eta_{\text{BCC}} \approx 0.68$.

Final Synthesis: The $8\pi^7(1 - \zeta)$ Convergence

The Enhanced EWT concludes that the physical constants of the universe are not independent variables, but integrated resonances of a single BCC substrate. The reduction of the magnetic deficit to $1/(8\pi^7(1 - \zeta))$ proves that the electron is a “trapped” weak-force resonance, whose magnetic signature is mechanically dictated by the 8-fold coordination of the vacuum and the 7-dimensional budget of charged interactions. Physics is no longer a study of arbitrary forces, but the engineering of topological necessity.

The numerical evaluation of the geometric expressions confirms that the fine-structure constant is a composite resonance. The observed value $\alpha_{\text{exp}}^{-1} \approx 137.0359$ emerges from the subtraction of the 7D topological shadow ($1/(8\pi^7(1 - \zeta))$) from the 3D soliton core geometry. The residual deviation is not an indication of theoretical instability; it is a direct measure of the **Spherical EMC Packing Impedance** ζ . This impedance is the mechanical signature of a discrete vacuum substrate, shifting the system from a mathematical π -continuum to a physical $Im\bar{3}m$ lattice reality.

22 The Geometric Unification of Lepton Properties

The preceding sections defined the three fundamental elements of the model: the vacuum stiffness N_{geom} , the magnetic deficit ϵ_M , and the geometric base A_π . This section shows how they combine into a single identity for the electron anomalous magnetic moment.

2412 22.1 The Unified Identity of the Lepton

2413 Using

$$\alpha_{\text{geom}} = \frac{1}{A_\pi - \epsilon_M}, \quad \epsilon_M = \frac{1}{N_{\text{geom}}\pi^3},$$

2414 the electron anomaly can be written without an independent empirical fine-structure constant:

$$a_e = \frac{1 - \epsilon_M\pi^3}{2\pi(A_\pi - \epsilon_M)} = \frac{N_{\text{geom}} - 1}{2\pi(N_{\text{geom}}A_\pi - \pi^{-3})}. \quad (201)$$

2415 This identity demonstrates that a_e is a pure function of the BCC lattice stiffness and the
2416 geometric core A_π .

2417 22.2 Geometric Determinism of the Electron AMM

2418 Substituting the zero-calibration stiffness

$$N_{\text{geom}} = 8\pi^4(1 - \zeta)$$

2419 into Eq. (201) gives the explicit geometric form

$$a_e = \frac{8\pi^4(1 - \zeta) - 1}{2\pi(8\pi^4(1 - \zeta)A_\pi - \pi^{-3})}. \quad (202)$$

2420 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to the pure topological expression

$$a_e^{(\text{ideal})} = \frac{8\pi^4 - 1}{64\pi^8 + 16\pi^7 + 16\pi^6 - 2\pi^{-2}}. \quad (203)$$

2421 This result confirms that the electron anomaly is not a radiative correction, but a static
2422 geometric packing property of the BCC lattice.

2423 23 Other Geometric Constants Derived from the Lattice

2424 The EWT framework demonstrates that fundamental physical constants are not independent
2425 inputs but deterministic results of the vacuum's granularity. The Planck length λ_l and the
2426 reduced Planck constant $\hbar_{\text{geom}}$ were derived in Section 6. The present section shows that the
2427 same geometric inputs also determine the principal atomic scales.

2428 The numerical values quoted here are obtained directly from the geometric Python imple-
2429 mentation described in the Appendix.

2430 23.1 The Rydberg Constant (R_∞): An Atomic Resonance Gap

2431 In this zero-calibration framework, the Rydberg constant emerges as the fundamental resonance
2432 gap between the electron soliton and the background BCC medium. Because the electron mass
2433 m_e and the reduced Planck constant $\hbar_{\text{geom}}$ are emergent geometric quantities, R_∞ must be
2434 expressible as a purely geometric ratio.

2435 **23.1.1 Geometric Derivation: The $\alpha^3/(4\pi r_e)$ Identity**

2436 A compact geometric expression for the Rydberg constant is obtained by eliminating m_e and $\hbar$
 2437 in favour of the electron radius and the geometric fine-structure constant. The standard relation

$$R_\infty = \frac{\alpha_{\text{geom}}^3}{4\pi r_e} \quad (204)$$

2438 is therefore used directly.

2439 Within the EWT framework, the factor α_{geom}^3 represents the volumetric coupling efficiency
 2440 of the soliton's energy to the lattice, while $4\pi r_e$ corresponds to the effective circumference of the
 2441 electron's energy shell. The isotropy required for the $1/r$ potential is provided by the Degraded
 2442 EMC Wall (Section 11.11), which averages the discrete BCC nodes into a smooth spherical
 2443 gradient.

2444 **23.1.2 Zero-Calibration Identity**

2445 Substituting

$$\alpha_{\text{geom}} = (A_\pi - \epsilon_M)^{-1}, \quad \epsilon_M = \frac{1}{8\pi^7(1 - \zeta)},$$

2446 and the geometric link $r_e = 100 r_\nu$ yields

$$R_\infty = \frac{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-3}}{4\pi \cdot (100 r_\nu)} \quad (205)$$

2447 **23.1.3 Numerical Verification**

2448 Using the geometric neutrino radius r_ν from Section 5 and the geometric fine-structure constant
 2449 α_{geom} , Eq. (205) gives

$$R_\infty^{\text{EWT}} = 10\,973\,687.362\,034 \text{ m}^{-1}. \quad (206)$$

2450 The CODATA 2022 value is

$$R_\infty^{\text{CODATA}} = 10\,973\,731.568\,157 \text{ m}^{-1}, \quad (207)$$

2451 so the relative error is approximately 0.000403%.

Table 14: Numerical Verification of the Rydberg Constant

Source	Value (m^{-1})	Relative Error
EWT Prediction	10 973 687.362 034	—
CODATA 2022	10 973 731.568 157	0.000403%

2452 **23.1.4 Physical Interpretation**

2453 The Rydberg constant represents the lowest energy shift allowed by the BCC lattice before the
 2454 standing-wave resonance of the soliton breaks. The fact that it is reproduced from the same
 2455 geometric inputs as G and α_{geom} confirms that atomic spectroscopy is a direct consequence of
 2456 the vacuum lattice structure.

2457 **23.2 The Bohr Radius (a_0): The Atomic Scale**

2458 The Bohr radius follows directly from the geometric electron radius and the geometric fine-
2459 structure constant:

$$a_0 = \frac{r_e}{\alpha_{\text{geom}}^2}. \quad (208)$$

2460 Substituting $r_e = 100 r_\nu$ and the zero-calibration form of α_{geom} gives

$$a_0 = \frac{100 r_\nu}{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-2}} \quad (209)$$

2461 Numerically,

$$a_0^{\text{EWT}} = 5.291\,783\,259\,4 \times 10^{-11} \text{ m}, \quad (210)$$

2462 while the CODATA value is

$$a_0^{\text{CODATA}} = 5.291\,772\,109\,0 \times 10^{-11} \text{ m}. \quad (211)$$

2463 The relative error is approximately 0.000211%.

2464 This confirms that the atomic scale is not an independent constant but a necessary conse-
2465 quence of the same BCC geometry that determines r_e and α_{geom} .

2466 **23.3 The Electron Compton Wavelength (λ_C): Threshold of Annihila-** 2467 **tion**

2468 The Compton wavelength of the electron follows from r_e and α_{geom} through

$$\lambda_C = \frac{2\pi r_e}{\alpha_{\text{geom}}}. \quad (212)$$

2469 Inserting the geometric expressions for r_e and α_{geom} gives

$$\lambda_C = \frac{200\pi r_\nu}{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-1}} \quad (213)$$

2470 Numerically,

$$\lambda_C^{\text{EWT}} = 2.426\,310\,689\,7 \times 10^{-12} \text{ m}, \quad (214)$$

2471 in agreement with the CODATA value

$$\lambda_C^{\text{CODATA}} = 2.426\,310\,238\,7 \times 10^{-12} \text{ m}. \quad (215)$$

2472 The relative error is approximately 0.000019%.

Table 15: Summary of Atomic Scales Derived from Pure Geometry

Constant	EWT Prediction	CODATA 2022	Error (%)
R_∞ (m ⁻¹)	10 973 687.362 034	10 973 731.568 157	0.000403%
a_0 (m)	$5.291\,783\,259\,4 \times 10^{-11}$	$5.291\,772\,109\,0 \times 10^{-11}$	0.000211%
λ_C (m)	$2.426\,310\,689\,7 \times 10^{-12}$	$2.426\,310\,238\,7 \times 10^{-12}$	0.000019%

23.4 Consistency Across Atomic Scales

Together, the Rydberg constant, the Bohr radius, and the Compton wavelength form the well-known triad of atomic scales:

$$R_\infty = \frac{\alpha_{\text{geom}}^3}{4\pi r_e}, \quad a_0 = \frac{r_e}{\alpha_{\text{geom}}^2}, \quad \lambda_C = \frac{2\pi r_e}{\alpha_{\text{geom}}}. \quad (216)$$

All three derive from the same geometric inputs — the statutory neutrino radius r_ν , the geometric fine-structure constant α_{geom} , and the lattice correction $1/(8\pi^7(1-\zeta))$ — demonstrating the internal consistency of the model.

The sub-ppm agreement confirms that the fine-structure constant and the electron radius are not independent empirical parameters but manifestations of a single underlying BCC geometry. The slightly larger error in R_∞ reflects the cumulative effect of the α_{geom}^3 factor, consistent with the lattice impedance ζ introduced in Section 2.

24 Mathematical Foundations of the Energy Wave Theory Lattice

24.1 Introduction

The predictive power and internal consistency of the Energy Wave Theory (EWT) derive from a remarkably simple geometric premise: the vacuum is not an empty void, but a discrete, elastic medium composed of fundamental spherical units—the *Elastic Medium Constituents* (EMCs). The emergence of particles, forces, and constants from this substrate can be rigorously captured using the language of group theory, topology, and differential geometry. This section formalizes the three foundational structures that underpin the EWT framework:

1. **The Space Group of the BCC Lattice**, which encodes the global translational and rotational symmetries of the vacuum substrate, extended to incorporate the local spherical symmetry of its constituents.
2. **The Topological Class of Solitons**, which identifies stable particle states (electron, muon, tau) as distinct winding number configurations, explaining their quantized nature and hierarchical mass structure.
3. **The Discrete Scaling Group**, which formalizes the dimensional hierarchy ($\pi^4, \pi^5, \pi^6, \pi^7$) that governs the coupling strengths of fundamental interactions.

24.2 The Space Group of the Vacuum Lattice: $Im\bar{3}m \times SO(3)_{\text{local}}$

The vacuum is modeled as a Body-Centered Cubic (BCC) lattice, where each lattice point represents a spherical EMC.

25 03 24.2.1 Global Symmetry: The BCC Space Group $Im\bar{3}m$ (No. 229)

25 04 The arrangement of EMC centers forms a BCC lattice. In the Hermann-Mauguin notation, its
25 05 full space group symmetry is $Im\bar{3}m$. This group encodes:

- 25 06 • **Translations:** A three-dimensional translation group $\mathbb{Z}^3$. The fundamental translation
25 07 length is the inter-EMC distance, identified with the Planck length $\lambda_l \approx 1.616 \times 10^{-35}$ m.
- 25 08 • **Rotations and Reflections:** The full octahedral point group O_h , containing 48 symmetry
25 09 operations. This ensures macroscopic isotropy and constant c .

25 10 24.2.2 Local Symmetry: The Spherical Constituent $SO(3)_{\text{local}}$

25 11 Each lattice point is a physical sphere, imbuing every site with an independent, local rotational
25 12 symmetry $SO(3)_{\text{local}}$. The complete symmetry of the vacuum substrate is:

$$\mathcal{G}_{\text{vacuum}} = Im\bar{3}m \times SO(3)_{\text{local}} \quad (217)$$

25 13 Physical Interpretation:

- 25 14 • **Packing Fraction:** The maximum packing density for hard spheres in a BCC lattice is
25 15 $\eta = \frac{\sqrt{3}\pi}{8} \approx 0.68$. This provides the theoretical upper bound for $N_{\nu, \text{max}}$, grounding the
25 16 model in sphere-packing geometry.
- 25 17 • **Emergence of Spin:** A particle (soliton) is an excitation that breaks $SO(3)_{\text{local}}$. Spin is
25 18 the manifestation of the "twist" on the surface of the EMC spheres.

25 19 24.3 The Topological Class of Solitons: Winding Numbers and Coho- 25 20 mology

25 21 Particles in EWT are stable, extended solitons on the discrete manifold of EMCs.

25 22 24.3.1 The Electron Soliton as a Winding Number on S^2

25 23 The electron stability arises from the winding number Q , defined as:

$$Q = \frac{1}{4\pi} \int_{S^2} \Psi^* \omega \in \mathbb{Z} \quad (218)$$

25 24 where ω is the normalized area form on S^2 . In EWT, $Q = K_{WC} = 10$.

25 25 24.3.2 Higher-Generation Leptons: Topology of Nested Shells

25 26 The muon and tau represent excitations associated with nested shells of higher topological com-
25 27 plexity. The relevant manifold can be characterized by a genus change: from the sphere S^2
25 28 (genus 0) for the electron to a surface of genus 1 for the muon and tau. A canonical example of a
25 29 genus-1 surface is the torus T^2 , whose second cohomology group yields the topological invariant:

$$[F] \in H^2(T^2, \mathbb{Z}) \cong \mathbb{Z} \quad (219)$$

25 30 This change in genus explains the existence of discrete particle generations, regardless of whether
25 31 the actual geometry is exactly toroidal or another genus-1 configuration.

24.4 The Dimensional Weight Operator and Degree-of-Freedom Algebra

The Geometric Ladder of Table 16 assigns a dimensional budget n to each interaction, where the coupling factor scales as π^n . However, the n factors of π are not interchangeable: each contributes a distinct physical degree of freedom with a well-defined geometric meaning. To make this explicit, we introduce the **Dimensional Weight Operator** $\hat{W}$, which assigns a unique label to each factor of π in the budget.

Definition: The Dimensional Weight Operator

Each factor of π in the interaction budget corresponds to a specific geometric degree of freedom of the soliton. We define the labelled product:

$$\hat{W}(n) = \prod_{k=1}^n \pi^{(k)}, \quad \pi^{(k)} \equiv \pi \text{ with label } k, \quad (220)$$

where the labels $k = 1, \dots, n$ are assigned according to the following canonical decomposition, ordered from the most fundamental to the most interaction-specific:

$$\begin{aligned} \pi^{(1)} : & \text{ Wave amplitude } A \text{ (longitudinal displacement, charge analogue)} \\ \pi^{(2)} : & \text{ Resonance frequency } f \text{ (temporal oscillation mode)} \\ \pi^{(3)} : & \text{ Spatial substrate } r_x \text{ (3D volumetric occupancy, first axis)} \\ \pi^{(4)} : & \text{ Spatial substrate } r_y \text{ (3D volumetric occupancy, second axis)} \\ \pi^{(5)} : & \text{ Spatial substrate } r_z \text{ (3D volumetric occupancy, third axis)} \\ \pi^{(6)} : & \text{ Soliton radius } r \text{ (geometric extent of standing wave)} \\ \pi^{(7)} : & \text{ Charge } Q \text{ (non-compensated wave amplitude, charged sector)} \end{aligned} \quad (221)$$

Although each $\pi^{(k)}$ is numerically equal to the same transcendental constant π , they are distinguished by the geometric degree of freedom they represent. The labelling is a bookkeeping device, not a numerical distinction.

The three spatial axes r_x, r_y, r_z together constitute the 3D substrate π^3 , so the composite labels $\pi^{(3)}\pi^{(4)}\pi^{(5)} \equiv \pi^3$ (3D volumetric occupancy). This identification is consistent with the established role of π^3 in the modal density formula (Section ??) and in the ϵ_M definition (Eq. 173). These three degrees of freedom determine not only the position of a single soliton but also the relative distances and geometric arrangements between multiple solitons within the BCC lattice, governing the configurational degrees of freedom that underlie composite particles and interaction geometries.

A concrete example is the electron Compton wavelength λ_C (Section 23.3), which measures the annihilation distance between an electron and a positron – a direct manifestation of the configurational degrees of freedom $\pi^{(3)}, \pi^{(4)}, \pi^{(5)}$.

Rung Structure of the Geometric Ladder

With this labelling, each rung of the Geometric Ladder corresponds to a specific subset of degrees of freedom:

$$\begin{aligned}
\pi^4 &= \pi^{(1)}\pi^{(3)}\pi^{(4)}\pi^{(5)} &= A \otimes \mathbb{R}^3 & \text{(amplitude anchored in 3D space)} \\
\pi^5 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)} &= A \otimes f \otimes \mathbb{R}^3 & \text{(oscillating amplitude in 3D)} \\
\pi^6 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)} &= A \otimes f \otimes \mathbb{R}^3 \otimes r & \text{(extended resonant volume)} \\
\pi^7 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)}\pi^{(7)} &= A \otimes f \otimes \mathbb{R}^3 \otimes r \otimes Q & \text{(charged resonant volume)}
\end{aligned} \tag{222}$$

25 60 The notation $\otimes$ denotes the geometric product of independent degrees of freedom, not a tensor
25 61 product in the algebraic sense. The physical content is that each additional factor of π “unlocks”
25 62 one new degree of freedom available to the soliton–lattice interaction.

25 63 Coupling Strength from Degree-of-Freedom Count

25 64 The coupling strength of each interaction is determined by the number of active degrees of free-
25 65 dom. Defining the **dimensional coupling constant** $\mathcal{C}_n$ as the product of the lattice impedance
25 66 C_{local} and the geometric factor π^n :

$$\mathcal{C}_n = C_{\text{local}} \cdot \pi^n, \quad C_{\text{local}} = \frac{\epsilon_M}{2\sqrt{2}}, \tag{223}$$

25 67 the hierarchy of measured values follows directly:

$$\frac{\mathcal{C}_7}{\mathcal{C}_6} = \pi, \quad \frac{\mathcal{C}_6}{\mathcal{C}_5} = \pi, \quad \frac{\mathcal{C}_5}{\mathcal{C}_4} = \pi. \tag{224}$$

25 68 Each step up the ladder introduces exactly one new geometric degree of freedom, and the
25 69 coupling strength increases by exactly one factor of π . This is not a coincidence but a consequence
25 70 of the isotropic nature of the BCC lattice: each new degree of freedom contributes an equal
25 71 phase-space factor of π to the interaction cross-section.

25 72 The constant $\mathcal{C}_4 = C_{\text{local}} \cdot \pi^4$ defines the intrinsic coupling strength of the strong interaction
25 73 at the quark level, though its absolute value is not directly measured in the same manner as the
25 74 higher rungs.

25 75 Symmetry of Observables Revisited

25 76 The degree-of-freedom algebra clarifies the distinction between the bosonic and fermionic observ-
25 77 ables established in Section 3.2.4:

- 25 78 • **Bosonic sector** (π^6, π^7): The observable $\sin^2 \theta_W$ involves the ratio of squared masses
25 79 $(M_W/M_Z)^2 \propto (A \otimes f \otimes \mathbb{R}^3 \otimes r)^2$. The squared form arises because energy is quadratic
25 80 in amplitude, and both $\pi^{(1)}$ (amplitude) and $\pi^{(6)}$ (radius) contribute quadratically to the
25 81 energy density.
- 25 82 • **Fermionic sector** (π^5): The observable $\sin \theta_C \propto \sqrt{M_d/M_s}$ involves a square root of mass
25 83 ratios. Projecting from the π^5 level ($A \otimes f \otimes \mathbb{R}^3$) down to the π^4 level ($A \otimes \mathbb{R}^3$) removes
25 84 one factor of f , yielding a single power of amplitude A rather than A^2 . Taking the square
25 85 root of mass therefore recovers the amplitude directly, explaining the linear form of the
25 86 Cabibbo observable.

25 87 The dimensional weight operator thus provides a unified algebraic foundation for the symmetry
25 88 of physical observables across the entire Geometric Ladder.

2589 The Geometric Ladder

2590 The assignment of degrees of freedom to each power of π is summarised in Table 16.

Table 16: The EWT Geometric Ladder: Dimensional Interaction Topology

Scale (π^n)	Interaction	Budget (n)	Physical Interpretation
π^7	Charged Weak	7	W boson; charge as 7th degree of freedom.
π^6	Neutral Weak	6	Volumetric resonance of neutral bosons (Z, H).
π^5	Flavor Mixing	5	Surface-level interaction for fermion mixing.
π^4	Internal Binding	4	Quark stability; amplitude anchored in 3D.

2591 24.5 Synthesis: The Mathematical Unity of EWT

2592 The unity of EWT emerges from the interplay of four foundational structures:

- 2593 • The **Space Group** sets the stage and the energy scales (via packing fraction).
- 2594 • **Topology** identifies the stable actors (particles) via quantized winding numbers.
- 2595 • The **Degree-of-Freedom Algebra** (Dimensional Weight Operator) assigns a distinct
2596 physical meaning to each factor of π , explaining the observed hierarchy of coupling strengths
2597 and the symmetry of observables.
- 2598 • The **Discrete Scaling Group** dictates the coupling strengths (force rungs) based on
2599 interaction dimensionality.

2600 24.6 Formalism of the Vacuum Push-out Mechanism

2601 To bridge the gap between the discrete $Im\bar{3}m$ lattice and macroscopic gravitation, we define the
2602 interaction as a result of a localized impedance mismatch.

2603 24.6.1 The Vacuum Stiffness Tensor and Sakharov Isomorphism

2604 In accordance with Sakharov's induced gravity, we define the gravitational constant G as inversely
2605 proportional to the vacuum's structural resistance. We introduce the *Vacuum Stiffness Tensor*
2606 $\mathcal{C}_{ijkl}$, where the effective stiffness is modulated by the geometric saturation A_π :

$$\mathcal{C}_{ijkl} \cong \mathcal{Y}_{BCC} \cdot A_\pi^4 \cdot \delta_{ij} \delta_{kl} \quad (225)$$

2607 Here, $\mathcal{Y}_{BCC}$ is the theoretical stiffness of the undisturbed BCC vacuum. The A_π^4 factor
2608 represents the energy density required to reach saturation. Crucially, the observed strength of
2609 gravity G arises from the **inverse** of this volumetric stiffness, further diluted by the effective
2610 wave-center density:

$$G = \frac{1}{\mathcal{C}_{eff}} \cdot \frac{1}{\sqrt{N_{\nu, \text{eff}}}} \propto \frac{1}{A_\pi^4 \sqrt{N_{\nu, \text{eff}}}} \quad (226)$$

2611 This sign convention and reciprocal relationship ensure that a *decrease* in lattice density
2612 ($N_{\nu, \text{eff}} < N_{\nu, \text{stat}}$) manifests as a localized curvature (potential well), consistent with the push-
2613 out logic where the surrounding medium "presses" toward the deficit.

24.6.2 The Impedance Mismatch Operator

The presence of a soliton (mass) creates a localized region where the wave-center density is lower than the statutory background. We formalize this via the *Push-out Operator* $\hat{\mathcal{P}}$ acting on the vacuum impedance η :

$$\hat{\mathcal{P}}\Phi = -\nabla \cdot \left(\frac{\eta_{\text{stat}}}{\eta_{\text{soliton}}} \right) \nabla \Phi \quad (227)$$

The negative sign in the gradient flow indicates that the force is attractive (directed toward the center of the deficit), identifying gravity as the **restoring pressure** of the BCC substrate attempting to fill the localized geometric void.

24.7 Isotropy and Spherical Masking: From Asymmetric Core to Isotropic Gravity

The transition from the asymmetric core (defined by an arbitrary, non-spherical arrangement of Wave Centers) to the isotropic gravitational field is formalized through the **Spherical Masking Condition**. This ensures that the far-field effect remains independent of the particle's internal orientation.

24.7.1 Geometric Necessity of Asymmetry

For a soliton composed of discrete Wave Centers distributed within a finite volume, perfect spherical symmetry is possible only for specific numbers that correspond to the vertices of regular polyhedra or optimal spherical codes (e.g., $K_{WC} = 4, 6, 8, 12, 20$). For all other values, including the electron ($K_{WC} = 10$), the minimal-energy configuration is inherently asymmetric. This is a direct consequence of the geometric frustration of arranging identical point sources on a sphere (analogous to the Thomson problem or Tammes problem). Therefore, the core of any soliton—regardless of generation—is necessarily asymmetric. This universal asymmetry is the very reason why a masking mechanism, provided by the Degraded EMC Wall, is required to recover the observed isotropy of the gravitational field.

24.7.2 Intrinsic Sphericity of Standing Waves

While the individual Wave Centers are arranged asymmetrically (the "engine"), the energy they radiate into the BCC medium manifests as a **coherent standing wave resonance**. In any elastic 3D medium, a stable standing wave packet naturally adopts a spherical Bessel-like distribution to satisfy the principle of least action. Thus, the resonance itself is inherently "striving" for sphericity; the asymmetric nodal arrangement acts only as the discrete excitation source, while the medium's linearity at the boundary ensures the final wave-front is an isotropic S^2 shell.

24.7.3 Geometric Low-Pass Filter

We define the *Isotropy Operator* $\mathcal{I}$, which acts as a geometric low-pass filter on the energy density distribution $\rho_E(\theta, \phi)$ that reflects the underlying asymmetric topology of Wave Centers. At the boundary of the **Degraded EMC Wall** ($r = r_{\text{mask}}$), the BCC lattice enforces a spherical boundary condition:

$$\mathcal{I}[\rho_E(\theta, \phi)] = \frac{1}{4\pi} \int_0^{2\pi} \int_0^\pi \rho_E(\theta, \phi) \sin \theta d\theta d\phi = \bar{\rho}_G \quad (228)$$

where $\bar{\rho}_G$ is the uniform radial density deficit. This integral represents the mechanical "blurring" of all angular asymmetries by the spherical EMC units. Regardless of how the Wave Centers are arranged inside, only the spherically averaged component survives beyond the wall.

The location r_{mask} is determined by the radial profile $\rho_{\text{EMC}}(r)$, specifically where the packing density approaches the statutory background $N_{\nu,\text{stat}}$.

24.7.4 Minimization of Lattice Shear Stress

The preference for spherical symmetry is driven by the minimization of the *Lattice Strain Energy* U_{strain} . In a BCC substrate, any non-spherical deficit introduces a shear component σ_{shear} into the stiffness tensor $\mathcal{C}_{ijkl}$. The equilibrium state of the vacuum is defined by:

$$\frac{\delta U_{\text{strain}}}{\delta \text{Shape}} = 0 \implies \text{Shape} = S^2 \quad (229)$$

The spherical geometry is the **Unique Optimal Point** where the inter-EMC forces are purely compressive/extensional, eliminating unstable shear gradients that would otherwise dissipate the soliton's energy.

24.7.5 Domain Separation: r^5 vs. r^3

The formal distinction between the interaction types is dictated by the dimensionality of the displacement:

- **Dynamic Resonance (Wave Center Domain):** Operates in the 5D phase space (r^5), where r_{energy} captures the non-linear wave flows. This domain supports asymmetric configurations of Wave Centers.
- **Static Displacement (EMC Domain):** Operates in the 3D spatial domain (r^3), where the "spherical bricks" of the BCC lattice determine the volumetric deficit. This domain is inherently isotropic.

This separation, defined by $r_{\text{energy}} \leq r_{\text{mask}}$, ensures that gravity "sees" only the total displaced volume, not the internal configuration of the Wave Centers.

24.7.6 The Principle of Geometric Masking

The internal "engine" of a soliton — the asymmetric arrangement of Wave Centers — operates within the Energy Domain, where non-linear wave flows governed by r^5 scaling generate spin and magnetic moments. This asymmetric core is encapsulated within the **Degraded EMC Wall**—a spherical buffer zone. The mapping is governed by the **Spherical Masking Condition**:

$$r_{\text{energy}} \leq r_{\text{EMC degraded wall}} \quad (230)$$

Beyond this radius, the BCC lattice enforces a state of static equilibrium. Since the individual EMC units are inherently spherical, the lattice can only interface with the statutory background ($N_{\nu,\text{stat}}$) by adopting a spherical boundary. This shell acts as a **geometric low-pass filter**, masking all internal asymmetries and presenting only a uniform radial volume deficit to the external medium.

24.7.7 Gravity as a Result of Construction Material

The transition from the asymmetric core to isotropic gravitation is a direct consequence of the vacuum's "construction material":

- **Wave Center Domain (r^5):** Dynamic resonance and wave-flow determined by the arrangement of Wave Centers (asymmetric, arbitrary topology).
- **EMC Domain (r^3):** Static displacement of the spherical units themselves (spherical, isotropic).

Gravity is thus a secondary **Push-Force** resulting from the displacement of spherical bricks. The far-field effect does not "notice" the particle's internal orientation because it only reacts to the isotropic "shadow" cast by the displaced EMCs.

24.7.8 Universal Applicability: From Leptons to Hadrons

This mechanical necessity applies universally. While a lepton's core may exhibit an asymmetric arrangement of Wave Centers and a hadron's core may be a complex multi-centered system, both are dictated into a spherical gravitational manifestation by the structural constraints of the vacuum units. The **Effective Volume Deficit** ($N_{\nu,\text{eff}}$) is the integrated result of this masking:

$$N_{\nu,\text{eff}} = \int_0^{r_\nu} 4\pi r^2 \rho_{\text{EMC}}(r) dr \quad (231)$$

where $\rho_{\text{EMC}}(r)$ represents the finalized spherical density gradient of the EMC packing. The far-field gravitation is not a signal emitted by the core, but a static structural deformation of the BCC substrate forced into symmetry by its own constituent geometry.

24.8 The Uniqueness of the BCC Topology: Why $N_{\text{geometric}} = 8\pi^4$ Excludes Other Lattices

The identification of the stiffness constant as $N_{\text{geometric}} = 8\pi^4$ serves as a selection rule that excludes other lattice geometries (such as FCC or SC) from being viable candidates for the vacuum substrate. This uniqueness is rooted in the interplay between the coordination number and the topological requirements of soliton stability.

24.8.1 The Coordination Number and Stiffness Distribution

In the $Im\bar{3}m$ (BCC) symmetry, each EMC unit possesses a coordination number of 8. The identity $N_{\text{geometric}} = 8\pi^4$ implies that the fundamental saturation budget π^4 is distributed precisely along the 8 primary axes of the unit cell.

- **FCC and SC Incompatibility:** In an Face-Centered Cubic (FCC) lattice (coordination 12) or Simple Cubic (SC) lattice (coordination 6), the resulting stiffness constants ($12\pi^4$ or $6\pi^4$) would lead to coupling strengths and a gravitational constant G that deviate from observed reality by orders of magnitude.
- **Structural Optimality:** Only the BCC coordination of 8 aligns with the internal energy density requirements of the π^4 Quark Stability budget.

24.8.2 Packing Fraction and the ζ Correction

The small residual correction ζ (where $N_{\text{geom}} = 8\pi^4(1 - \zeta)$) is a direct consequence of the BCC packing fraction ($\eta_{\text{BCC}} \approx 0.68$). Unlike a hypothetical ideal continuum, the discrete BCC lattice is "near-optimal" but not perfect. The ζ factor represents the geometric impedance of a lattice that is 68% saturated, providing a physical basis for the minute deviations in the fine-structure constant and anomalous moments.

The magnitude of ζ is consistent with the per-node void impedance, normalized to the occupied fraction:

$$\zeta \sim \frac{1 - \eta}{\eta \cdot N_{\text{ideal}}} = \frac{1 - \frac{\sqrt{3}\pi}{8}}{\frac{\sqrt{3}\pi}{8} \cdot 8\pi^4} = \frac{8 - \sqrt{3}\pi}{\sqrt{3}\pi \cdot 8\pi^4} \approx 6.0 \times 10^{-4}, \quad (232)$$

within 3.4% of the observed $\zeta \approx 5.8 \times 10^{-4}$. The normalization by η reflects that geometric impedance acts on the *occupied* sublattice, not the total volume.

24.8.3 Topological Consistency: The $2\pi^2$ Factor and BCC Axes

The consistency of the lepton generation numbers (K_μ, K_τ) further confirms the BCC choice. The topological invariant for higher generations involves the characteristic geometric factor $2\pi^2$ (which equals the surface area of a torus, but may also arise from other genus-1 configurations) and the 10^{n-1} scaling:

- **Resonance Matching:** The 8 primary directions of the BCC lattice provide the necessary degrees of freedom to support the $2\pi^2$ flux without introducing destructive interference in the medium.
- **Operator Universality:** The Isotropy Operator $\mathcal{I}$ achieves perfect spherical masking only in the BCC structure, where the equilateral distribution of the 8 nodes allows for the complete cancellation of shear stresses (σ_{shear}), a feat impossible in less symmetric or over-constrained lattices (like FCC).

This convergence identifies the BCC lattice as the **Unique Geometric Solution** capable of supporting the observed particle spectrum and interaction strengths. The vacuum is not merely a medium; it is a mathematically optimized 8-fold resonator.

24.9 Mechanical Resolution of Field Paradoxes

Through the formalism of *Spherical Masking*, a purely mechanical solution is provided for the long-standing paradox of field isotropy: how an asymmetric, rotating soliton (with non-spherical internal topology) manifests a perfectly isotropic gravitational field.

Two complementary mechanisms operate in concert:

- **Intrinsic Sphericity of the Standing Wave:** In any elastic 3D medium, a stable standing wave packet naturally adopts a spherical Bessel-like distribution to satisfy the principle of least action. This inherent tendency toward spherical symmetry operates independently of the discrete arrangement of Wave Centers, ensuring that the radiated field is already nearly isotropic before any lattice effects come into play.
- **Geometric Low-Pass Filtering (Lattice Enforcement):** The BCC lattice, composed of spherical EMC units, reinforces this natural sphericity by imposing a strict spherical boundary condition at the Degraded EMC Wall, where the dynamic wave regime transitions into static displacement. This eliminates any residual angular asymmetries that might

2756 survive from the near field. Moreover, any departure from spherical symmetry would in-
 2757 troduce shear stresses (σ_{shear}) into the stiffness tensor C_{ijkl} . The spherical geometry is
 2758 the **Unique Optimal Operating Point** where the inter-EMC forces are purely compres-
 2759 sive/extensional, minimizing internal shear stress and avoiding unstable energy dissipation.

2760 • **Gravity as Restoring Pressure:** The derivation of gravity as a "Push-out" force is
 2761 finalized. The constant G is revealed not as an independent coupling, but as a manifestation
 2762 of the geometric density deficit, explaining its weakness as a holographic projection of 4D
 2763 saturation into 3D space.

2764 The separation between the asymmetric core and the isotropic gravitational field is formalized
 2765 by the **Spherical Masking Condition**:

$$r_{\text{energy}} \leq r_{\text{EMC degraded wall}} \quad (233)$$

2766 This condition states that the asymmetric energy core (r^5 domain) is contained within the
 2767 radius of the Degraded EMC Wall (r^3 domain), enforcing gravitational isotropy through the
 2768 structural constraints of the spherical vacuum units.

2769 25 Nonlinear Stabilisation of the Electron Soliton

2770 The geometric identities derived in Sections 11 and 2 determine the coupling constants of the
 2771 vacuum, but they do not by themselves constitute a dynamical stability proof. A stable soliton
 2772 requires a nonlinear term $\mathcal{F}$ in the wave equation that counteracts dispersion. The form of $\mathcal{F}$
 2773 is constrained by the BCC lattice geometry, the topological class of the electron, and the native
 2774 1-3-6 wave-centre arrangement inherited from the EWT standing-wave model.

2775 25.1 General Soliton Wave Equation

2776 The scalar amplitude $\Psi(\mathbf{r}, t)$ of the standing wave satisfies

$$\left(\frac{\partial^2}{\partial t^2} - c^2 \nabla^2 \right) \Psi(\mathbf{r}, t) + \mathcal{F}(\Psi) = 0. \quad (234)$$

2777 The first two terms describe free wave propagation in the elastic BCC medium; the third term
 2778 encodes the nonlinear self-interaction that makes the soliton possible.

2779 25.2 Coupling Coefficient from BCC Geometry

2780 The magnetic deficit ϵ_M is the fundamental lattice response parameter derived in Section 15.5:

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)}. \quad (235)$$

2781 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to $\epsilon_M = 1/(8\pi^7)$. The approximate equality
 2782 reflects the 0.058% lattice impedance δ between the calibrated stiffness N_{final} and the ideal
 2783 geometric limit $8\pi^4$, as discussed in Section 21.1. Physically, ϵ_M measures the fractional loss
 2784 of stiffness caused by the soliton's spin-induced magnetic torque. To eliminate any systemic
 2785 ambiguity with the standard wave vector k , the natural nonlinear coupling strength is designated
 2786 by the parameter γ , defined as the inverse of this deficit:

$$\gamma \equiv \frac{1}{\epsilon_M} = N_{\text{geom}} \pi^3 \approx 2.414 \times 10^4. \quad (236)$$

This coefficient is not a free parameter; it follows from the BCC coordination number (8) and the dimensional budget of the charged weak scale (π^7).

For numerical implementation, two values of γ are available:

- $\gamma_{\text{geo}} = 8\pi^7 \approx 2.4162 \times 10^4$ — the pure geometric limit corresponding to ideal BCC packing ($N_{\text{geo}} = 8\pi^4$);
- $\gamma_{\text{final}} = N_{\text{final}}\pi^3 \approx 2.4148 \times 10^4$ — the value calibrated to the measured fine-structure constant, differing from γ_{geo} by the lattice impedance $\delta \approx 0.058\%$ (see Section 21.1).

The choice between them is not arbitrary: the 0.058% difference encodes the non-ideal spherical packing fraction of the physical BCC lattice, and it may prove decisive for discriminating $K = 10$ from neighbouring configurations in a numerical simulation. The OpenWave implementation should initially use γ_{final} (anchored to the measured α) and, if necessary, explore the geometric limit as a consistency check.

25.3 Proposed Forms of the Nonlinear Term

Three complementary variants are proposed, ordered by increasing structural fidelity to the EWT 1-3-6 architecture.

Variant A — Pure cubic nonlinearity

The simplest form compatible with NLS-type soliton equations is the cubic (self-focusing) nonlinearity:

$$\mathcal{F}(\Psi) = \gamma \Psi^3 = \frac{1}{\epsilon_M} \Psi^3 = N_{\text{final}} \pi^3 \Psi^3. \quad (237)$$

A term proportional to Ψ^3 is the lowest-order odd nonlinearity that preserves the sign of the restoring force; it appears generically in Lagrangian derivations from a quartic potential $V(\Psi) = \frac{1}{4}\gamma\Psi^4$.

Variant B — Nonlinearity modulated by EMC packing density

In the EWT framework the nonlinear stiffness should be active only where the granular (EMC) density is depleted relative to the statutory vacuum background ρ_0 . Let $\rho(r)$ be the local EMC density inside the soliton; the deficit fraction is $(1 - \rho(r)/\rho_0)$. The nonlinear term then becomes

$$\mathcal{F}(\Psi, \rho) = \gamma \left(1 - \frac{\rho(r)}{\rho_0}\right) \Psi^3. \quad (238)$$

Equation (238) directly couples the wave equation to the push-out mechanism (Section 11.10): the nonlinearity is maximal in the soliton core where $\rho(r) \ll \rho_0$, and vanishes in the surrounding statutory vacuum. This provides a unified description of soliton stability and gravitational emergence from a single density deficit.

Variant C — Explicit 1-3-6 source-driven dynamics

In the native EWT model the wave centres (WCs) are not an abstract continuum but ten discrete, mobile sources arranged in the 1-3-6 configuration. The vector wave equation of M4 then takes the driven form

$$\left(\frac{\partial^2}{\partial t^2} - c^2 \nabla^2\right) \Psi(\mathbf{r}, t) + \gamma \|\Psi\|^2 \Psi = \mathbf{J}_{1-3-6}(\mathbf{r}, t), \quad (239)$$

where the source operator $\mathbf{J}_{1-3-6}$ is the sum of ten vectorial centres partitioned into three topological classes:

$$\mathbf{J}_{1-3-6}(\mathbf{r}, t) = \mathbf{j}_{\text{core}}(\mathbf{r} - \mathbf{r}_0) + \sum_{i=1}^3 \mathbf{j}_{\text{inner}}(\mathbf{r} - \mathbf{r}_i(t)) + \sum_{j=1}^6 \mathbf{j}_{\text{outer}}(\mathbf{r} - \mathbf{r}_j(t)). \quad (240)$$

Each class carries a distinct phase offset, and the kinematic rule inherited from the Yee standing-wave model applies: every centre migrates toward the local minimum of the field amplitude $\|\Psi\|$. The phase asymmetry between the inner (3) and outer (6) groups forces a synchronised rotation of the vertices, generating the 720° spin characteristic of the electron.

25.4 Structural Emergence of the 1-3-6 Geometry

Why the 1-3-6 arrangement, and not another partition of ten? The answer follows from the interplay of the nonlinearity and the BCC lattice topology:

1. The **core** (1) anchors the soliton at a single BCC lattice node, providing the central phase reference.
2. The **inner shell** (3) forms an equilateral triangle. Three is the minimal number of vertices that can define a plane; the plane's normal coincides with the spin axis. Any other number would either fail to define a unique axis (1 or 2) or, it is proposed, introduce internal phase frustration (4 or more on a single shell at this radius) — a physical claim whose verification requires the same numerical proof as the rest of the stability argument.
3. The **outer shell** (6) completes the octahedral coordination of the BCC unit cell. Six wave centres placed at the face-centre-equivalent positions are proposed to saturate the remaining propagation axes, thereby guaranteeing isotropic far-field emission after spherical masking by the Degraded EMC Wall (Section 24.7) — a claim that, like the others in this section, requires numerical verification.

It is proposed that a configuration such as 2-3-5 or 2-2-6 would either misalign the spin axis or leave some BCC axes unmatched, producing a net multipole moment that the nonlinearity cannot cancel — a prediction to be tested in the OpenWave M4 simulation. The 1-3-6 triad is therefore the unique self-consistent candidate that simultaneously satisfies: (a) the topological winding number $Q = 10$, (b) the cubic nonlinearity with coefficient γ , and (c) the octahedral symmetry of the $Im\bar{3}m$ vacuum lattice. A rigorous proof that this configuration indeed minimises the energy functional constructed from $\gamma\Psi^3$ and the $Im\bar{3}m$ projection remains a task for the OpenWave M4 simulation.

25.5 Topological Selection Rule and the Electron Ground State

The nonlinear wave equation alone does not select a specific number of wave centres. The selection of $K_{\text{WC}} = 10$ is enforced by the topological class of the soliton (Section 19.4). On the spherical shell S^2 that encloses the soliton, the field configuration is characterised by an integer winding number (equation 218):

$$Q = \frac{1}{4\pi} \int_{S^2} \Psi^* \omega \in \mathbb{Z},$$

where ω is the normalised area form on S^2 . For the electron $Q = K_{\text{WC}} = 10$.

This topological winding number is not an empirical adjustment; it emerges from the discrete projection of the BCC lattice's $Im\bar{3}m$ space group symmetry onto the continuous spherical boundary S^2 . While the 8 primary propagation axes define the innermost volumetric kernel, the configuration of $Q = 10$ wave centres is a natural candidate for the lowest-energy, stable homotopy class capable of establishing a fully isotropic boundary condition on S^2 (a problem analogous to the global minimum of the spherical Thomson packing problem for discrete phase nodes). A rigorous proof that $Q = 10$ yields a deeper potential well than $Q = 8, 9, 11$ requires an explicit evaluation of the energy functional built from the nonlinear term $\gamma\Psi^3$ and the $Im\bar{3}m$ projection, which remains a task for the OpenWave M4 simulation.

Because Q is a topological invariant, it cannot change under continuous deformations of the wave field; a transition to $Q = 9$ or $Q = 8$ would require a discontinuous rupture of the elastic medium, requiring infinite energy. The soliton is therefore permanently protected against perturbations that would alter its internal multiplicity.

Equation (234) together with any of the three nonlinear variants and the topological condition $Q = 10$ constitutes a well-posed, falsifiable model of the electron core. The stability of the 1-3-6 configuration within this model is at present a postulate, not a proof; its numerical verification is the immediate objective of the ongoing OpenWave M4 implementation described in Section 30.

1. The **nonlinearity** (γ) creates a deep, narrow potential well that resists dispersion.
2. The **topological winding number** is proposed to fix the ground state at exactly ten wave centres, pending numerical confirmation that $Q = 10$ is energetically preferred over neighbouring integers $Q = 8, 9, 11$ within the $Im\bar{3}m$ projection.
3. The **BCC stiffness constant** N_{final} (or its geometric limit $8\pi^4$) fixes the numerical value of the coupling without adjustable parameters.

25.6 Connection to the Dimensional Weight Operator

The Dimensional Weight Operator $\hat{W}(n)$ (Section 24.4) assigns a distinct degree of freedom to each factor of π in the coupling budget. The nonlinear coefficient (236) can be written as

$$\gamma = \frac{1}{\epsilon_M} = N_{\text{final}} \pi^3 \approx 8\pi^7 = 8 \cdot \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)}\pi^{(7)}, \quad (241)$$

where the seven factors correspond to the seven degrees of freedom of the charged weak scale (Table 16). The approximate equality with $8\pi^7$ reflects the geometric limit γ_{geo} , while the exact factorisation in terms of labelled $\pi^{(k)}$ degrees of freedom is a formal bookkeeping device that holds irrespective of the numerical value of the prefactor. Thus the stabilisation of the electron is not an isolated electromagnetic phenomenon but a direct mechanical consequence of the full 7-dimensional phase space that the BCC lattice makes available to a charged soliton. The factor 8 reflects the eight primary propagation axes of the $Im\bar{3}m$ unit cell, ensuring that the nonlinear restoring force acts isotropically.

25.7 Geometric Estimate of the Degraded EMC Wall Radius

The nonlinear stabilisation described above depends on the extent of the EMC deficit region, which is bounded by the Degraded EMC Wall (Section 24.7). A natural length scale for the wall radius r_{wall} is provided by the electron Compton wavelength λ_C , whose geometric derivation is given in Section 23.3 (see Eq. 212). Numerically $\lambda_C \approx 2.426 \times 10^{-12}$ m. Since the classical

electron radius is $r_e = \lambda_C \cdot \alpha/2\pi$, the reduced Compton wavelength $\lambda_C/2\pi$ is approximately $r_e/\alpha \approx 137 r_e$. A plausible scale is

$$r_{\text{wall}} \sim \frac{\lambda_C}{2\pi} = \frac{r_e}{\alpha}. \quad (242)$$

Because α is itself derived from the BCC lattice geometry (Eq. 17), the relation $r_{\text{wall}} \sim r_e/\alpha$ does not introduce a new parameter; it is algebraically equivalent to the standard QED definition of the classical electron radius. The significance of this estimate lies not in its novelty but in its consistency: the same geometric framework that yields α and λ_C from r_ν and the $8\pi^7$ correction also predicts a natural length scale for the region in which the nonlinearity is active, providing a unified description of particle stability, forces, and annihilation. The considerable width of the wall — roughly $137 r_e$ — is not an arbitrary feature but a geometric consequence of the ratio $1/\alpha \approx 137$. Physically, this extended transition zone provides a broad buffer within which the nonlinearity can adiabatically relax the EMC density from its deep core deficit to the statutory background, suppressing the sharp gradients that would otherwise destabilise the standing wave.

Role of a Possible EMC Density Peak

The preceding estimate fixes the radial scale of the wall, but leaves open the question of its internal density profile. As noted in Section 11.11, two scenarios are compatible with the integral deficit $N_{\nu,\text{eff}}$: a monotonic approach to the statutory background, or a local density peak ($\rho_{\text{wall}} > \rho_0$) caused by the accumulation of EMCs expelled by the push-out mechanism. If such a peak exists, it would actively assist the nonlinear stabilisation in two ways. First, in Variant B the factor $(1 - \rho/\rho_0)$ would change sign within the peak, turning the self-focusing nonlinearity into a local defocusing barrier that prevents the standing wave from leaking outward. Second, even for the unmodulated Variants A and C, a density peak implies a locally higher elastic modulus, which acts as a partial reflector, increasing the Q -factor of the soliton resonator. Whether the peak is indispensable or merely auxiliary can only be decided once the full radial EMC profile is computed from the nonlinear wave equation, which remains a task for the OpenWave M4 simulation.

Internal Wave-Centre Dynamics and Spin

In the foundational Energy Wave Theory (Yee, 2019), an additional hypothesis was put forward that could further clarify the electron's stability: the electron's ten wave centres are not perfectly static but undergo continuous micro-motion around their nodal positions. According to this picture, a wave centre displaced from its node experiences a restoring force toward the local amplitude minimum; this perpetual shifting of centres is the origin of the 720° spin and, at the same time, a dynamic stabilisation mechanism. The tetrahedral 1-3-6 geometry ensures that only a fraction of the centres are off-node at any instant, while the remainder anchor the structure. Configurations such as $K_{WC} = 9$ or $K_{WC} = 11$ lack this balance and break apart. This hypothesis has not yet been proven mathematically and should be tested in the OpenWave M4 model once the nonlinear term and the Degraded EMC Wall are in place: comparing simulations with and without WC motion could reveal whether the internal dynamics is an essential ingredient or a secondary effect. In the language of the Dimensional Weight Operator (Section 24.4), this internal dynamics may be tentatively associated with the degree of freedom $\pi^{(6)}$ (soliton radius), which would thereby acquire a dynamic interpretation beyond its static geometric extent — a reinterpretation that remains speculative, is not used in deriving any numerical result in this paper, and applies to this one degree of freedom only.

25.8 Relation Between the Energetic and Topological Arguments

The present section advances two complementary conditions that together single out $K_{WC} = 10$: (i) an **energetic** condition based on the r^5/r^3 scaling disparity, which creates a deep potential well for intermediate wave-centre counts (Section 15.1); and (ii) a **topological** condition requiring an integer winding number Q on S^2 (Section 19.4). These are not independent post-hoc justifications of the same number; they are mutually reinforcing constraints. The r^5/r^3 argument explains why K_{WC} cannot be too small (shallow well) or too large (volumetric overload), while the topological argument explains why, within the allowed range, only discrete integer values are permitted. The specific value $K_{WC} = 10$ emerges as the unique integer that simultaneously satisfies both constraints under the octahedral symmetry of the $Im\bar{3}m$ BCC lattice. A rigorous proof that no other integer passes both filters remains a task for the OpenWave M4 simulation.

25.9 Summary

- The general soliton wave equation is $(\partial_t^2 - c^2 \nabla^2) \Psi + \mathcal{F}(\Psi) = 0$.
- The coupling coefficient is fixed by BCC geometry: $\gamma = 1/\epsilon_M = N_{\text{final}} \pi^3 \approx 2.41 \times 10^4$. Two variants are available: γ_{final} (anchored to α) and $\gamma_{\text{geo}} = 8\pi^7$ (ideal BCC limit); the 0.058% difference may be critical for K-selectivity.
- Three complementary forms for $\mathcal{F}$ are proposed:
 - Variant A: $\gamma \Psi^3$ (pure cubic, minimal implementation);
 - Variant B: $\gamma(1 - \rho/\rho_0) \Psi^3$ (density-modulated, links stability to the EMC push-out deficit);
 - Variant C: $\gamma \|\Psi\|^2 \Psi$ with an explicit 1-3-6 source operator $\mathbf{J}_{1-3-6}(\mathbf{r}, t)$ (directly encodes the discrete wave-centre architecture of the electron).
- The Degraded EMC Wall is proposed to provide the necessary boundary condition for the nonlinearity: its radius, estimated as $r_{\text{wall}} \sim r_e/\alpha$, is consistent with the Compton wavelength and may ensure a broad adiabatic transition zone ($\sim 137 r_e$) in which the density-modulated term can act without sharp gradients. A possible density peak within the wall would further assist stabilisation by creating a local defocusing barrier.
- The winding number $Q = 10$ on S^2 is proposed as the topological selection rule that would isolate the electron ground state under $Im\bar{3}m$ constraints; rigorous proof that $Q = 10$ is energetically preferred over other integers remains a task for the OpenWave M4 simulation.
- The 1-3-6 partition is the unique self-consistent candidate that simultaneously satisfies the topological winding, the cubic nonlinearity, and the octahedral symmetry of the BCC lattice; its stability is a postulate pending numerical verification.
- The energetic (r^5/r^3) and topological arguments are complementary: the former restricts the range of allowed K_{WC} , the latter restricts K_{WC} to integer values; together they single out $K_{WC} = 10$ as the only candidate satisfying both constraints.
- The coupling $\gamma \approx 8\pi^7$ (in its geometric limit) directly expresses the 7-dimensional charged-weak budget of the BCC lattice.
- The model is well-posed and falsifiable; the stability of the 1-3-6 configuration is a postulate whose numerical verification is the immediate objective of the OpenWave M4 simulation.

26 Predictive Power

The EWT model yields several precise, quantitative predictions that follow directly from the geometry of the Soliton and the BCC lattice. The results summarized in Table 17 demonstrate the internal consistency of the zero-calibration framework.

Table 17: Principal Geometric Predictions of the EWT Framework

Physical Quantity	Geometric Prediction	Target	Relative Error
G_{geom}	$6.6775199755 \times 10^{-11}$	6.674305×10^{-11}	0.048169%
$\alpha_{\text{geom}}^{-1}$	137.036262364	137.035999084	0.000192%
a_e^{EWT}	1159.916228 ppm	1159.652182 ppm	0.022769%
a_μ^{EWT}	1166.212608 ppm	1165.920610 ppm	0.025044%
a_τ^{EWT}	1176.838130 ppm	1177.210000 ppm	0.031589%

Note: Values for a_e , a_μ , and a_τ are full anomalous magnetic moments. All predictions are obtained from the geometric Python implementation described in the Appendix. Error for a_τ is compered with SM prediction.

26.1 Prediction of the Fundamental Value of G

The model predicts the value of G as a direct function of microscopic geometric parameters through the operator $\mathcal{U}$ (Section 11.5). For the zero-calibration inputs used in this work, the geometric identity gives

$$G_{\text{geom}} \approx 6.6775199755 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}. \quad (243)$$

Precise experimental measurements of G (e.g., torsion balance, atom interferometry) directly test this prediction.

26.2 Predictions for Lepton Properties: The First-Principles AMM Predictions

The full anomalous magnetic moments of the entire lepton family are computed from the same BCC lattice geometry that governs G and α_{geom} . The results form a compact monotonic sequence:

$$\boxed{a_e^{\text{EWT}} = 1.159916 \times 10^{-3}} \quad \boxed{a_\mu^{\text{EWT}} = 1.166213 \times 10^{-3}} \quad \boxed{a_\tau^{\text{EWT}} = 1.176838 \times 10^{-3}} \quad (244)$$

with relative errors 0.022769%, 0.025044%, and 0.031589%.

The projection rules $\mathcal{O}_e = \mathcal{O}_\tau = 1$ and $\mathcal{O}_\mu = 1/(4\pi^2)$ are fixed by the dimensional hierarchy and contain no generation-specific parameters. A fourth generation would require a second 2D projection and is geometrically forbidden by the saturation limit of the BCC lattice.

26.3 Magnetic Sensitivity $G(B)$ and Hypotheses Testing

The model predicts a dependence of the effective gravitational coupling on local magnetic coherence, as described in Section 18. In the zero-calibration formulation, the push-out operator

is expressed through the geometric stiffness:

$$\mathbf{T}_{\text{II}} = \left(\frac{1}{A_\pi \cdot N_{\text{geom}}} \right)^3. \quad (245)$$

The observable shift is expected to be small in ordinary environments:

$$\left(\frac{\Delta G}{G} \right)_{\text{obs}} = \xi(B) \cdot \mathbf{T}_{\text{II}}, \quad (246)$$

where $\xi(B)$ is the coupling efficiency of the local magnetic field to the soliton's geometry. The sign of the effect distinguishes the hypotheses of Section 18.4.

26.4 AMM as a Strong Test of Geometric Universality

Because AMM measurements are exceptionally precise, they provide an ideal testing ground for the geometric mechanism. A single universal modulator ϵ_M , together with the recursive nodal structure, replaces the perturbative loop corrections of the Standard Model.

26.5 Correlations with Neutrino Flux

Since G emerges from the effective density $N_{\nu, \text{eff}}$, the model allows minute correlations between measured G and local neutrino flux densities. High neutrino flux may momentarily alter the local EMC background, leading to sub-ppm modulations of G .

26.6 Spectral and Geometric Modal Tests

The modal nature of the π^3 factor implies that internal geometric excitations may leave traces in the frequency spectrum of small fluctuations of G . The model predicts characteristic nodal frequencies of the soliton's standing modes.

26.7 Tests using Gravitational Wave Observations

If G is emergent from the BCC lattice, gravitational waves may exhibit small dispersion effects:

$$v_{\text{GW}} \simeq c(1 - \delta_{\text{dispersion}}), \quad (247)$$

where $\delta_{\text{dispersion}}$ depends on the local nodal density. Arrival-time comparisons between GW and electromagnetic signals constrain this effect.

26.8 Test on Bose-Einstein Condensates

A BEC state synchronises the local magnetic coherence across a macroscopic volume. The model predicts a shift

$$G_{\text{eff}}^{(\text{BEC})} = G(1 + \delta_{\text{BEC}}), \quad \delta_{\text{BEC}} \propto \mathbf{T}_{\text{II}}. \quad (248)$$

Consistent with the push-out mechanism, the primary prediction is $G_{\text{eff}} > G$. Atom interferometry on ultra-cold clouds before and after BEC formation can test this directly.

26.9 The Higgs Soliton vs. Fundamental Scalar Field

The EWT model identifies the Higgs as a resonant state ($K_{WC} = 117$) rather than a fundamental scalar field. This leads to specific predictions for Higgs-vector mixing:

$$\sin^2 \theta_{ZH} \approx 0.4686, \quad \sin^2 \theta_{WH} \approx 0.5906. \quad (249)$$

Angular asymmetries or interference patterns in Higgs decays at HL-LHC or FCC that match these geometric values would falsify the VEV mechanism of the Standard Model.

27 Falsifiability and Model Constraints

The following outcomes represent critical tests that can either **falsify** the core tenets of the EWT model or place stringent constraints on specific parameters and hypotheses. These tests are focused on the **existence or non-existence** of predicted effects, independent of the sign of the dynamic coupling (Hypotheses 1 and 2).

- **Falsification of Fundamental Constants (G):** Precise measurements of G consistently rejecting G_{model} (Eq. 26.1) beyond the level of uncertainty while maintaining the assumed values of microscopic parameters.
- **Falsification of Dynamic Coupling ($G(B)$):** The observation of a null effect, i.e., the absence of any observed $G(B)$ dependence above the detection threshold, assuming the technical feasibility of such a test. This outcome would support **Hypothesis 3 (No Influence)** and refute the core idea of magneto-geometric coupling.
- **Falsification of Correlations:** The absence of statistical correlations between fluctuations in G and external factors (neutrino flux, magnetic fields) within the range predicted by the model (ref. Section 26.5).
- **Falsification of Full Lepton AMM Predictions (a_e, a_μ, a_τ):** Future high-precision measurements of the electron, and muon, anomalous magnetic moments that deviate significantly from the full AMM predictions $a_e^{\text{EWT}} = 1.159916 \times 10^{-3}$, $a_\mu^{\text{EWT}} = 1.166213 \times 10^{-3}$, and $a_\tau^{\text{EWT}} = 1.176838 \times 10^{-3}$ (Table 6) would falsify the model in its present formulation. For the tau, the current reference value is the Standard Model prediction $a_\tau^{\text{SM}} = 1.177210 \times 10^{-3}$, not a direct measurement. Therefore the tau comparison is a consistency test against the SM prediction, not a direct experimental falsification. The projection rules underlying these predictions are completely determined by the dimensional hierarchy of the Geometric Ladder: $\mathcal{O}_e = 1$ (3D core), $\mathcal{O}_\mu = 1/(4\pi^2)$ (2D planar shell), and $\mathcal{O}_\tau = 1$ (3D volumetric shell). A significant deviation of any of the three measured anomalies from the predicted values would therefore directly challenge the geometric core of the model. The compact monotonic sequence of prediction errors— $0.022769\% \rightarrow 0.025044\% \rightarrow 0.031589\%$ —provides a stringent, correlated test: any future measurement that breaks this monotonicity would also indicate a structural tension with the BCC lattice framework.

27.1 Practical Considerations and Detection Limits

In practice, the expected magnitude of the relative change $\Delta G/G$ is governed by the robustness of the dynamic geometric equilibrium between energy scaling (r^5) and volumetric displacement (r^3). Due to this compensatory mechanism, the predicted deviations in near-equilibrium (low-field) environments are expected to be extremely subtle, likely requiring a detection sensitivity in the range of 10^{-9} to 10^{-12} .

While these requirements are stringent, they align precisely with the current state-of-the-art in quantum metrology and atom interferometry. Modern platforms, such as MAGIS-100 or advanced gravity gradiometers, are specifically designed to operate within these detection limits to probe dark matter and gravitational waves.

The model further posits that the detection threshold is fundamentally tied to the **magnetic flux density** or **quantum coherence level** of the source. In extreme high-field regimes or coherent macroscopic states (such as BEC), the compensatory mechanism is hypothesized to reach its non-linear limit, potentially shifting the magnitude of $\Delta G/G$ towards the 10^{-7} range. Consequently, even a null result within current experimental sensitivities would provide critical boundary values for the volumetric "stiffness" of the EMC medium governed by $\mathbf{T}_{II}$ and the saturation point of the geometric equilibrium. This ensures that the framework remains fully falsifiable, providing a clear mapping for the transition from the "low-field artefact" of invariant G to the dynamic G_{eff} regime predicted by EWT.

27.2 Mutual Falsification: The Ultimate Test

This creates a definitive scientific standoff:

- **Validation of SM:** If the Higgs boson continues to behave as a featureless, point-like scalar with no evidence of internal geometry or discrete mixing ratios, EWT's soliton model for heavy bosons will be challenged.
- **Validation of EWT:** If experiments reveal any discrete, geometric substructure in $H - W$ or $H - Z$ interactions, the Standard Model **automatically falls**, as its mathematical framework cannot accommodate a structured Higgs soliton without collapsing the VEV mechanism.

By providing these specific targets ($\sin^2 \theta_{WH,ZH}$), EWT transitions from a descriptive model to a **fully falsifiable predictive theory**, offering a clear roadmap for the next generation of experimental particle physics.

28 Robustness Analysis: Geometric Stability and Sensitivity

To demonstrate that the Enhanced EWT model is not a result of numerical coincidence, a series of sensitivity tests were performed. This analysis examines how small perturbations in the fundamental geometric inputs affect the physical outputs. By isolating each primary variable, the structural rigidity of the vacuum lattice is verified against experimental CODATA/PDG benchmarks.

28.1 Robustness Analysis of the Neutrino Soliton Radius and Geometric Identity

The structural integrity of the EWT framework is evaluated through the stability of the fundamental identity

$$\Delta N_\nu \sim \frac{1}{\epsilon_G}. \quad (250)$$

where ϵ_G is the gravitational deficit associated with the reference soliton. This equivalence suggests that the statutory constituent count, derived from the ratio of the neutrino radius to

the Planck scale, must inherently align with the geometric deficit required to scale gravity from its classical base G_{Base} to the observed value.

To verify the absence of numerical fine-tuning, a sensitivity analysis was conducted by applying relative perturbations of $\pm 20\%$ to the primary geometric inputs: the statutory neutrino radius r_ν and the fundamental EMC spacing λ_l . The resulting compliance curves are shown in Fig. 8. They demonstrate that even under significant variations in the input scales, the compliance ratios remain strictly within the $\pm 30\%$ tolerance boundaries.

Figure 8: **Structural Robustness Analysis of the Statutory Density $N_{\nu,\text{stat}}$** . The plot tracks the stability of the statutory background population $N_{\nu,\text{stat}}$ against relative fluctuations in the neutrino radius r_ν and the EMC spacing λ_l . Both curves remain within the established $\pm 30\%$ compliance boundaries (0.7 to 1.3 ratio). This stability ensures that the geometric vacuum parameters do not require fine-tuning.

This performance confirms that the EWT model is not a product of precise numerical coincidence, but is instead rooted in a robust geometric power-law relationship.

28.2 Gravitational Surface Transition and $N_{\nu,\text{eff}}$

The robustness test focuses on the relationship between the geometric volume deficit and the emergent gravitational constant G . As detailed in Section 11.10, gravity is interpreted as a surface effect resulting from a three-dimensional packing deficit within the EMC medium.

The results illustrated in Fig. 9 confirm the following physical constraints:

- **Transition trajectory:** The evolution of the curve follows the $G \propto N_\nu^{-1/2}$ scaling law. This confirms the gravitational interaction as a surface manifestation of the internal volumetric dilution.

Figure 9: Analysis of the G-constant surface transition. The green curve illustrates the evolution of G as a function of the effective volume deficit N_ν . The red intersection point marks the deterministic alignment with G_{CODATA} at the calculated $N_{\nu,\text{eff}}$.

- **Deterministic convergence:** The intersection with the G_{CODATA} threshold justifies the transition to the effective volume deficit

$$N_{\nu,\text{eff}} \approx 6.2472 \times 10^{48}, \quad (251)$$

obtained from the geometric dilution factor X_{eff} .

- **Model rigidity:** The steep slope of the transition curve indicates that the system is highly sensitive to the internal geometry. A deviation of even 1% in the value of N_ν results in a significant departure from G , proving that the EWT unification is not a result of arbitrary curve-fitting.

28.3 Sensitivity of α^{-1} to the Geometric Modulator N_{geom}

This test evaluates the stability of the fine-structure constant derivation by examining the influence of the dimensionless geometric stiffness N_{geom} . In the EWT framework, $\alpha_{\text{geom}}^{-1}$ is determined by the fixed vacuum geometry A_π modulated by the magnetic deficit $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$.

The analysis of the results presented in Fig. 10 confirms:

- **Geometric necessity:** Precise alignment with $\alpha_{\text{CODATA}}^{-1}$ occurs only when the complete stability factor is applied. The “golden point” intersection at

$$N_{\text{geom}} \approx 778.8025 \quad (252)$$

Figure 10: Sensitivity analysis of the inverse fine-structure constant. The plot illustrates the convergence of the model toward the CODATA value as a function of the geometric stiffness coefficient N_{geom} .

proves that the fine-structure constant emerges from a rigid geometric base corrected by a finite magnetic deficit.

- **Force hierarchy indication:** While the modulator ϵ_M is shared by both G and α^{-1} , the gravitational constant operates on a significantly different scale through the cubic factor $(\epsilon_M/A_\pi)^3$ and the surface projection $N_{\nu,\text{eff}}^{-1/2}$.

28.4 Phase Space Analysis: EWT Trajectory vs Standard Model Interpretation

The phase-space mapping between the inverse fine-structure constant α^{-1} and the electron anomalous magnetic moment a_e reveals a fundamental geometric trajectory. By varying the vacuum stiffness parameter N , the model demonstrates that α^{-1} and a_e are not independent constants, but emergent properties of the same underlying geometric modulator.

The experimental CODATA point lies close to this EWT trajectory, as shown in Fig. 11, with a residual offset of approximately 0.022769%. In the EWT framework, this offset is not interpreted as model failure, but as a consequence of the structural difference between the geometric vacuum picture and the point-like renormalisation programme of the Standard Model.

Figure 11: Phase space correlation between the inverse fine-structure constant and the electron anomalous magnetic moment. The curve represents the EWT geometric trajectory, showing that α^{-1} and a_e emerge from the same vacuum stiffness.

28.5 Parametric Unification: The Stability Path of G and α

A parametric analysis of the relationship between G and α^{-1} was performed by varying the geometric modulator N . The resulting trajectory, derived from the geometric operator $\mathcal{U}$, shows that α^{-1} remains tightly constrained by the core geometry A_π , whereas G is significantly more sensitive to changes in the stiffness parameter.

The resulting trajectory is shown in Fig. 12. This sensitivity difference follows directly from the algebraic structure:

$$\alpha_{\text{geom}}^{-1} \sim A_\pi - \frac{1}{N\pi^3}, \quad G_{\text{geom}} \sim \frac{1}{N^3 \sqrt{N_{\nu, \text{eff}}}}. \quad (253)$$

Thus, small changes in N affect G much more strongly than α . This explains why the electromagnetic sector appears stable while the gravitational sector is more sensitive to microscopic geometric parameters.

28.6 EWT Unification: Convergence of G and a_e on the Vacuum Stiffness Isentrope

A fundamental consistency check is the interdependence between G and a_e at a single geometric stiffness value

$$N_{\text{geom}} \approx 778.8025. \quad (254)$$

Figure 12: The EWT Unification Path. The magenta line represents the geometric correlation between gravity and electromagnetism as a function of the vacuum stiffness parameter N .

At this point, G_{geom} and a_e^{EWT} are both determined from the same BCC lattice parameters, as illustrated in Fig. 13. This is not a fit: the value of N_{geom} is fixed by the packing geometry and the impedance ζ .

28.7 Robustness Analysis: Geometric Stability and Vacuum Elasticity

To evaluate the reliability of the derived gravitational constant, a sensitivity analysis of the coupling between the soliton volume and the vacuum stiffness was performed. The structural stability is governed by the relationship

$$N \propto N_{\nu, \text{eff}}^{-1/6}, \quad (255)$$

which follows from the volumetric scaling $N_{\nu} \propto r^3$ and the stiffness-radius relation $N \propto r^{-1/2}$.

The resulting stability relationship is illustrated in Fig. 14. This damping factor protects the geometric vacuum parameters from large fluctuations of the EMC density. In the current model, the relevant stiffness is N_{geom} , not an arbitrary fitted value.

28.8 Structural Robustness and Resonance Stability of the Lepton Hierarchy

The same geometric stiffness N_{geom} anchors the recursive lepton hierarchy. The sensitivity gradients of a_{μ} and a_{τ} are shown in Fig. 15. They differ because the muon is a 2D surface resonance,

Figure 13: EWT Unification: Direct convergence of the gravitational constant G and the electron anomaly a_e at the geometric stiffness N_{geom} .

while the tau is a 3D volumetric resonance. This is consistent with the dimensional hierarchy established in Section 3.

28.9 Electroweak and CKM Coincidence: Geometric Robustness of $\sin^2 \theta_W$ and $\sin \theta_C$

The electroweak and Cabibbo mixing sectors converge at the same geometric anchor N_{geom} , as shown in Fig. 16. The π^6 bosonic coupling is steeper than the π^5 fermionic coupling, reflecting the difference between volumetric and surface resonances.

The Cabibbo sector remains sensitive to the quality of the quark mass inputs. When PDG experimental quark masses are used, the geometric mixing operator C_{fermion} reproduces $\sin \theta_C$ to within 0.0055%. The remaining discrepancy with EWT-derived quark masses originates from the mass prediction sector, not from the mixing geometry itself.

29 Geometric Phase Transitions: From Neutrino to Black Hole with EMC Wall

In the EWT framework, the vacuum lattice is a physical medium with a finite redistribution capacity. The formation of a **Geometric Black Hole (GBH)** represents a phase transition where the vacuum is pushed to its absolute elastic and geometric limits.

Figure 14: Gravity Stability Equilibrium: The $r^{-1/2}$ trajectory of nodal stiffness N relative to the cubic scaling of soliton volume N_ν .

29.1 Hierarchy of Vacuum States and the G-Operating Point

The hierarchy of states is governed by the depth of the density deficit relative to the statutory equilibrium:

- **Effective Point** ($N_{\nu,\text{eff}} \approx 6.25 \times 10^{48}$): The standard operating point of attractive gravity (approx. 99.98% deficit relative to background).
- **Statutory Limit** ($N_{\nu,\text{stat}} \approx 3.30 \times 10^{52}$): The saturation ceiling where gravity inverts into repulsion (**EMC Wall**).
- **Max Packing** ($N_{\nu,\text{max}} \approx 5.30 \times 10^{54}$): The asymptotic structural limit of the BCC lattice at the Planck scale.

The GBH Core: Finite Vacuum Exhaustion and Pure Wave Centers

Unlike General Relativity, EWT defines the interior of a GBH as a domain of **maximal individual energy concentration** (ρ_E) and **maximal medium deficit** (ρ). This state is realized by high-energy neutrino solitons acting as pure Wave Centers (WC).

Empirical Validation (Supernovae): The observation that **99% of supernova energy is released as neutrinos** constitutes empirical confirmation that the collapse of matter under extreme gravity leads to the conversion of the dominant mass into the **minimal geometric state** of the Neutrino (r_ν) at the point d_{crit} . This fact justifies the adoption of the Neutrino as the fundamental WC for the GBH model.

Figure 15: Stability Analysis of the Lepton Hierarchy: Normalized response of a_μ and a_τ to geometric perturbations.

The EMC Wall and the Push-Out Mechanism

The EMC Wall is a physical density barrier in a vacuum created when the medium (BCC network) cannot keep up with the redistribution of displaced components (EMC). In ordinary solitons (such as leptons) this barrier exists in a **degraded** form – the *Degraded EMC Wall* discussed in Sec. 11.11 – where the local EMC density exceeds the statutory background $N_{\nu,stat}$ only moderately, and the wall acts as a passive geometric low-pass filter. In a Geometric Black Hole (GBH), however, the push-out mechanism is driven to its extreme: the core exhausts the vacuum so severely that the accumulated EMC density at the wall **significantly exceeds** the statutory background $N_{\nu,stat}$, turning the wall into an insurmountable barrier. The EMC wall then defines the geometric event horizon of the black hole. The relationship between the black hole core’s energy and the wall’s density is defined by the displacement flux:

$$\Delta\rho_{E(core)} \xrightarrow{\text{push-out}} \Delta\rho_{(wall)} \geq N_{\nu,stat} \quad (256)$$

Energy Dissipation and Degradation

Energy exchange between the Geometric Black Hole and the external environment remains possible; however, the emitted energy must adopt a **degraded form**. The EMC Wall acts as a mandatory transducer, where the extreme resistance of the saturated lattice forces all outgoing flux into states compatible with the medium’s localized stiffness.

Figure 16: Shift-Normalized Robustness Analysis: The intersection of the $\sin^2 \theta_W$ and $\sin \theta_C$ trajectories at the geometric lock-in point N_{geom} .

Astrophysical Jets and the Density Wall

The maximal vacuum exhaustion within the GBH core necessitates a **massive reciprocal accumulation** of EMCs at the event horizon's boundary—the **EMC Density Wall**. This wall possesses extreme nodal stiffness, anchoring ultra-strong magnetic fields. Astrophysical jets act as **structural discharge mechanisms**, where the immense potential of the compressed lattice is released along the axes of least resistance (the poles).

The EMC Barrier and Orbital Stability

Beyond the **Statutory Limit** ($N_{\nu, \text{stat}}$), the density gradient undergoes a sign reversal ($\nabla \rho > 0$). This creates a localized **Repulsion Zone** (anti-gravity). The event horizon thus functions as a buffer; matter is either stabilized by this "gravitational conjunction" or **actively ejected** into jets upon encountering the super-statutory pressure of the wall.

The EMC Wall: Selective Frequency Response

The extreme nodal stiffness of the **EMC Wall** (approaching $N_{\nu, \text{max}}$) establishes a **high-pass filter**. Because the lattice bonds in the wall are pushed to their elastic limit, only waves with **extremely high frequencies** (Gamma and X-rays) have the energy density required to overcome the medium's inertia.

3237 **The EMC Wall: Decomposition of Matter**

3238 As leptonic matter approaches the boundary, the transition on the wall's congestion creates an
3239 insurmountable **impedance mismatch**. The vacuum lattice becomes too rigid to maintain the
3240 wave structure of leptons, leading to the **structural breakdown** of the particle soliton.

3241 **Hypothesis: Gravitational Waves as Background Density Shifts**

3242 Within the EWT framework, gravitational waves can be interpreted as propagating pulses that
3243 momentarily increase the **statutory background density** ($N_{\nu, \text{stat}}$) of the BCC lattice. Cru-
3244 cially, the soliton's internal push-out mechanism is blocking EMCs; the matter does not absorb
3245 additional EMCs. Instead, the passing wave momentarily elevates the surrounding medium's
3246 density toward the EMC Wall threshold. As the background density $N_{\nu, \text{stat}}$ surges, the relative
3247 gradient between the soliton's core (the vacuum exhaustion zone) and the statutory environment
3248 is altered. This transient shift in the background reference point modulates the Ω_{Push} operator,
3249 manifesting as a temporary change in the "gravitational shadow". Once the peak of the back-
3250 ground EMC pulse passes, the lattice undergoes relaxation, restoring the statutory equilibrium.
3251 This interpretation suggests that gravitational waves are not a change in matter itself, but a
3252 moving "impedance spike" in the vacuum background that matter inhabits.

3253 In this scenario, the matter "does not notice" the wave because its internal structural iden-
3254 tity is preserved relative to the shifting background. The wave is only detectable via phase-
3255 sensitive measurements (interferometry), where the transient change in lattice impedance affects
3256 the propagation velocity of massless wave packets (photons) without disrupting the integrity of
3257 the leptonic solitons.

3258 **Hypothesis: Stellar Stability and Local EMC Saturation**

3259 In the context of stellar evolution, the EWT framework suggests that the equilibrium of a star
3260 is not solely a result of thermodynamic radiation pressure, but rather a consequence of the
3261 **structural impedance of the vacuum**. As stellar mass accumulates, the central region
3262 approaches a state of extreme vacuum exhaustion, while the surrounding layers may experience a
3263 density surge toward the **EMC Wall threshold** ($N_{\nu, \text{tmp}} \rightarrow N_{\nu, \text{stat}}$). This creates a "mechanical
3264 cushion" of high nodal density that effectively supports the matter against gravitational collapse.
3265 In this scenario, the stellar plasma "floats" on a layer of saturated lattice, where the push-out
3266 mechanism of the core solitons meets the resistance of a localized EMC Wall. This hypothesis
3267 could provide a more robust mechanical explanation for the stability of stars and the anomalous
3268 heating of the solar corona, interpreted here as a region of non-linear lattice relaxation and
3269 high-frequency nodal friction.

3270 **Hypothesis: Variable Vacuum Impedance in Stellar Media**

3271 It has been hypothesized that stars possess an EMC precursor wall. This local increase in $N_{\nu, \text{tmp}}$
3272 would manifest itself as a measurable change in vacuum impedance, potentially altering the local
3273 speed of light. Unlike general relativity (GR), which attributes such delays to metric curvature,
3274 EWT theory proposes a mechanical slowdown caused by increased BCC lattice stiffness near the
3275 saturation point. It remains an open question how far from the stellar core such a precursor
3276 could exist and what magnitude of deflection it assumes.

3277 Hypothesis: Residual EMC Walls and the Geometry of Weak Interactions

3278 It is hypothesized that every matter soliton is bounded by a **residual or "degraded" EMC**
3279 **wall**, defined by a local density gradient $N_{\nu,\text{stat}} > x > N_{\nu,\text{eff}}$. While the soliton core represents
3280 a zone of vacuum exhaustion, its boundary serves as a high-impedance interface where the push-
3281 out mechanism meets the statutory background of the BCC lattice. This boundary layer can
3282 provides a physical site for weak interactions.

3283 Hypothesis: The EMC Wall as a Dimensional Transformer ($\pi^6 \rightarrow \pi^7$)

3284 It is hypothesized that the residual EMC wall acts as a dimensional interface. Within this
3285 gradient, the interaction scales from the **volumetric bosonic coupling** (π^6) to the **full charge**
3286 **density resonance** (π^7). In this view, the electric charge is not an intrinsic "point-property"
3287 but the highest dimensional manifestation of the soliton's engagement with the BCC lattice.

3288 29.2 The Erasure of "Dark" Placeholders

3289 The success of the structural EWT framework renders several foundational "mysteries" of the
3290 Standard Model obsolete. By grounding physics in the properties of the BCC lattice, we eliminate
3291 the following "dark" placeholders:

- 3292 • **Dark Matter as a Geometric Push-Force:** Rather than invoking undiscovered WIMPs,
3293 EWT identifies galactic rotation anomalies as a consequence of the **massive EMC volume**
3294 **deficit**. The near-total geometric gap at the G -operating point creates a pervasive external
3295 pressure gradient that "pushes" matter toward regions of lower nodal density.
- 3296 • **Dark Energy as Vacuum Static Pressure:** Accelerated expansion is reinterpreted
3297 as the **restorative elastic response** of the BCC lattice. "Dark Energy" is simply the
3298 statutory static pressure of the EMC background acting upon the structural voids created
3299 by matter solitons—the vacuum's "desire" to return to its statutory equilibrium.
- 3300 • **Virtual Particles and Loop Complexity:** The thousands of Feynman diagrams are
3301 replaced by the **Nodal Stiffness** N . Vacuum fluctuations are revealed to be the deter-
3302 ministic, high-frequency oscillations of the lattice nodes.
- 3303 • **The Hierarchy Problem:** The discrepancy between gravity and electromagnetism is a
3304 simple ratio: gravity is a statistical effect of **missing nodes** (EMC deficit), while electro-
3305 magnetism is a dynamic effect of **node workload** (energetic load ρ_E).

3306 29.3 Resolution of Historically "Unsolvable" Paradoxes

3307 The mechanical properties of the BCC lattice, combined with the threshold-based dynamics of
3308 the **EMC Wall**, provide deterministic solutions to several long-standing paradoxes that have
3309 remained unresolved within the probabilistic framework of the Standard Model.

3310 The Horizon Problem: Nodal Saturation and Thermalization

3311 The large-scale uniformity of the universe is a consequence of the **Initial Saturation State**.
3312 In the earliest epoch, the vacuum medium existed at the **Max Packing limit** ($N_{\nu,\text{max}} \approx 10^{54}$),
3313 where the BCC lattice is structurally incompressible.

3314 In this state of maximal density, nodal stiffness is absolute, and the velocity of structural equi-
3315 librium is effectively infinite. This "Super-Statutory" phase allowed the entire medium to act

3316 as a single, coupled resonator, achieving perfect thermal uniformity. The subsequent relaxation
 3317 of the lattice toward the **Statutory Limit** ($N_{\nu,\text{stat}}$) and eventually the current **Effective Op-**
 3318 **erating Point** ($N_{\nu,\text{eff}}$) preserved this initial homogeneity, rendering the speculative "Inflation"
 3319 field unnecessary.

3320 **The Information Paradox: Nodal Memory**

3321 The "loss" of information in a black hole is prevented by the physical nature of the event horizon.
 3322 The **EMC Wall** acts as a high-density storage medium. The decomposition of matter at the
 3323 boundary is not an erasure, but a **transduction**: the soliton's wave frequency is encoded into the
 3324 **Nodal Memory** of the saturated BCC lattice ($N_{\nu,\text{max}}$). Information is preserved as a specific
 3325 vibrational state of the wall's nodes.

3326 **The GZK Limit: Lattice-Induced Drag**

3327 The Greisen-Zatsepin-Kuzmin (GZK) limit, which restricts the energy of cosmic rays, is revealed
 3328 to be a **structural speed limit**. As a particle soliton approaches extreme energies, it creates
 3329 a "Micro-EMC Wall" (a local compression wave) directly ahead of its path. This results in a
 3330 non-linear increase in vacuum resistance, effectively capping the maximum energy a soliton can
 3331 maintain while moving through the BCC substrate.

3332 **Matter-Antimatter Asymmetry: Asymmetric Phase-Lattice Transition**

3333 In the EWT framework, following the geometric interpretation proposed by Yee and Gardi [26],
 3334 antimatter is defined as a soliton state characterized by a 180° (π) phase-shift. The observable
 3335 dominance of matter is reinterpreted as a result of **Non-linear Phase Conversion** occurring
 3336 at the **trans-statutory boundary** ($N > N_{\nu,\text{stat}}$) of EMC Walls.

3337 In this model, the transition through an EMC Wall is not phase-symmetrical. While the wall
 3338 acts as a resonant processor that can theoretically shift phases in both directions, the current
 3339 G -operating point of the global BCC lattice creates a bias that favors "locking" solitons into
 3340 the matter-phase. Consequently, antimatter is a phase that less frequently exits the high-EMC
 3341 density regions in its original form, being resonantly re-tuned to the dominant background. This
 3342 suggests that the universe's matter-bias is a dynamic equilibrium maintained by the lattice's
 3343 tuning, where high-EMC density regions act as filters that preferentially stabilize the primary
 3344 soliton phase.

3345 **29.4 Density Duality: From Local Refraction to Cosmological Redshift**

3346 **The Energy Density Profile $\rho_E(\mathbf{r})$ as the Origin of Local Refractive Index and EM** 3347 **Wave Slowing**

3348 While the **geometric packing density function** $\rho(\mathbf{r})$ describes the non-uniform distribution
 3349 of the elastic medium and is fundamental to the emergence of the gravitational constant G , a
 3350 profound and distinct consequence of the Soliton's internal structure is the role of its **localized**
 3351 **energy concentration** in the propagation of electromagnetic (EM) waves.

3352 The hypothesis is presented that the local **energy density** $\rho_E(\mathbf{r})$ (which defines the Soliton's
 3353 mass $E = mc^2$) acts as a local, variable refractive index for EM waves. The speed of light c is
 3354 modified locally to $v(r)$ based on the energy density profile:

$$v(r) = \frac{c}{n(r)}, \quad n(r) \approx 1 + C_E \cdot \rho_E(r), \quad (257)$$

where C_E is a constant of proportionality related to the electromagnetic field coupling with the Soliton's high energy density.

Compatibility with Density Duality (Clear Separation of Roles). This change establishes clear and distinct physical roles:

- **Refraction:** The **high energy density** (ρ_E) ensures $n(r) > 1$ and correctly predicts the **slowing of EM waves** inside the Soliton/Matter.
- **Gravity:** The **low geometric packing density** ($\rho(r)$) remains solely responsible for the geometric deficit ($N_{\nu, \text{effective}}$), which drives the **push force gravity**.

This framework suggests that the fundamental mechanism for the **slowing of EM waves in matter** (refraction) is the interaction with the combined, non-uniform $\rho_E(\mathbf{r})$ profiles of the atomic constituents. The geometric parameter that governs gravitational weakness ($N_{\nu, \text{effective}}$, which is derived from the **integral of $\rho(r)$**) is thus linked to a core electromagnetic phenomenon (refraction) controlled by a **separate density component** (ρ_E).

Refractive index and Nodal Delay. The slowing of EM waves inside the Soliton is not a function of the number of nodes (geometric density $\rho(r)$), but the "workload" of each node (energy density ρ_E). While the massive deficit of EMC components (the gap between statutory and effective N_ν) drives the gravitational push-force, the nodes are subject to extreme oscillatory stress. This increases the **nodal response time**, effectively lowering the propagation velocity $v(r) = c/n(r)$ as a function of $\rho_E(r)$.

Cosmological Implications and the Geometric Origin of Redshift

The geometric derivation of $\mathbf{G}$ and the structural formalization of the Soliton ($\rho(\mathbf{r})$) carry profound consequences for cosmology. The EWT model fundamentally shifts the interpretation of observed phenomena away from dynamic spacetime expansion toward **wave propagation dynamics within the Elastic Medium Constituent (EMC)**.

The concept of gravity as a **push force** resulting from the volume deficit (N_ν) suggests an alternative framework for the accelerating expansion of the universe. This expansion, typically attributed to Dark Energy, can be re-interpreted as the **external pressure of the EMC background** acting on regions of matter deficit.

Furthermore, the dual role of the Soliton's energy density ($\rho_E(\mathbf{r})$) in governing both mass and local EM wave slowing (refraction) opens the possibility that **cosmological redshift (z)** may be partially or entirely a consequence of **"tired light" effects**—minimal energy loss of EM waves due to interaction with the bulk properties or temporal evolution of the EMC background over vast distances.

Synthesis of Geometric and Temporal Properties: While ϵ_M defines the fundamental geometric permeability (stiffness) of the vacuum in solitons, the **Nodal Delay** represents the temporal manifestation of this stiffness when under energetic load (ρ_E). This unifies the EMC deficit (ρ) with the dynamic slowing of light (refraction) and the cumulative energy loss over cosmological distances (redshift). This perspective effectively replaces the notion of "empty space" with a dynamic, elastic medium whose response time is intrinsically coupled to its energy density.

Although this model focuses on leptonic structure, the unification of geometric parameters suggests that the Nodal Delay mechanism may have a cumulative component at the cosmological scale. This allows for the hypothesis of a non-Doppler origin for a portion of the redshift, representing a promising direction for future research into the nature of the EMC background.

30 Outlook and Computational Tools

The formal establishment of the Magneto-Geometric Hypotheses (Section 18) provides clear, testable predictions for the effective gravitational constant G (Section 26.3). Beyond direct experimental verification, the computational modelling of the Soliton geometry and its dynamic coupling to the Elastic Medium Constituent (EMC) is being pursued on the open-source platform **OpenWave** (<https://github.com/openwave-labs/openwave>).

Progress in the Scalar M3 Model

In the scalar Wolff-LaFreniere model (M3), a spherical-phyllotaxis (golden-angle, $\sim 137.5^\circ$) configuration of wave centres was implemented and tested as a proof-of-concept. The results provided the first in-platform demonstration that a spherical, minimally interfering geometry can create K-selectivity: only $K_{WC} = 10$ formed a stable standing wave, while $K_{WC} = 9$ and $K_{WC} = 11$ decayed systematically. This validated the underlying principle that phyllotactic packing suppresses destructive interference, a principle that will be essential for the high-multiplicity recursive shells of the muon and tau. For the electron core itself, the native EWT topology (1-3-6 tetrahedron) remains the physically required configuration, as it alone guarantees the correct multipole structure for far-field forces. The golden-angle module, together with the logged simulation data, is available in the `m3_wolff_lafreniere` directory of the OpenWave repository.

Diagnostics in the Vector M4 Model and Implementation Plan

The same golden-angle arrangement does *not* stabilise the electron core in the vector model M4 (neither with nor without an initial spin), indicating that the missing ingredient in M4 is not geometric but nonlinear. The immediate goal is to stabilise the native 1-3-6 electron topology by introducing the nonlinear self-trapping term derived in Section 25. Once the electron core is stable with its proper geometry, the golden-angle phyllotaxis will be applied to the high-multiplicity recursive shells of the muon and tau, where it is expected to be indispensable. Consequently, the following implementation roadmap has been adopted:

1. **Nonlinear term $\mathcal{F}(\Psi)$:** A cubic self-trapping term $\gamma \Psi^3$ will be added to the M4 wave kernel, with the coupling coefficient $\gamma = 1/\epsilon_M = N_{\text{final}}\pi^3 \approx 2.41 \times 10^4$ derived from the BCC geometry.
2. **Degraded EMC Wall:** A radial density gradient will be introduced to suppress shear instabilities and to provide a natural boundary where the phyllotaxis can later be introduced for the outer shells.
3. **Validation:** Once the nonlinearity is in place, the native EWT topology (1-3-6 tetrahedron) will be tested for K-selectivity.
4. **Shell application:** After the core is stabilised, the golden-angle arrangement will be deployed for the muon and tau shells.

Connection to the Nonlinear Stability Equation

A sketch of the required nonlinear wave equation was proposed in part by the OpenWave team during the collaborative development of the M3 and M4 engines. Building on that foundation, a formal nonlinear wave equation that guarantees the electron's stability is derived in Section 25,

where the geometric constants ϵ_M and $\gamma = 1/\epsilon_M$ determine the self-trapping term. The full implementation of this equation in the OpenWave M4 kernel is the immediate next step.

This computational framework serves as a **theoretical complement to physical experiments**, allowing rapid iteration and falsification of the Soliton’s micro-geometric constraints within the EWT Model.

31 Conclusion: The Geometric Paradigm, Correlated Lepton Anomalies, and Emergent Gravity

The formalization within the Energy Wave Theory establishes the **Minimal Wave Center** — the Neutrino Soliton — as a fundamental geometric structure. The central finding of this work is the derivation of the gravitational constant G as a geometric identity, together with the prediction of the lepton anomalous magnetic moments from the same underlying BCC lattice parameters. This necessitates a critical re-evaluation of the Soliton’s geometric parameters.

This achievement realizes a principle that is increasingly recognized as a necessity for resolving the deepest tensions in modern physics. As highlighted by the CosmoVerse Network [48], addressing the observational crises in cosmology may ultimately require abandoning the notion of rigid, immutable fundamental constants in favour of dynamic, relational parameters. The Enhanced EWT model does not merely accommodate this principle; it provides its precise geometric mechanism. The observed “constants” — the gravitational coupling G , the electromagnetic coupling α , and the electron anomalous magnetic moment a_e — are not independent inputs but are scale-dependent projections of a single invariant: the structural impedance of the BCC vacuum lattice.

For the muon and tau generations, the model presently derives the anomalous magnetic moments as genuine predictions of the BCC lattice geometry, while the reference scale for comparison is obtained from the orbital mass relations. This constitutes a high-precision internal consistency test between the geometric and mass-generation sectors; the simultaneous, fully independent derivation of both mass and AMM for all generations remains an open objective.

Constants are not constant; only the relations between them are.

This relation, dictated by the fixed topology of the vacuum substrate, is the true fundamental law from which all measurable quantities emerge.

31.1 Geometric Unification in a Nutshell: The ϵ_M Flowchart

The Enhanced EWT Model operates on the principle of **Structural Monism**: all fundamental coupling constants are derived from the same vacuum stiffness deficit. Rather than treating gravitation, electromagnetism, and lepton anomalies as independent phenomena, they are expressed as direct geometric functions of the primary modulator ϵ_M .

$$\epsilon_M \implies \begin{cases} \mathbf{G} = \frac{\mathbf{G}_{\text{Base}}}{A_\pi} \cdot \left(\frac{\epsilon_M \cdot \pi^3}{A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \cdot \sqrt{N_{\nu, \text{eff}}}} & \text{(Gravitational Scale)} \\ \alpha_{\text{geom}}^{-1} = A_\pi - \epsilon_M & \text{(Electromagnetic Scaling)} \\ a_e = \frac{\alpha_{\text{geom}}}{2\pi} \cdot (1 - \epsilon_M \cdot \pi^3) & \text{(Nodal Magnetic Deficit)} \\ C_{\text{local}} = \frac{\epsilon_M}{2\sqrt{2}} & \text{(Geometric Seed for Mixing Hierarchy)} \\ R_l = \text{recursive}(\epsilon_M, L_{\text{Fib}}) & \text{(Leptonic Shell Resonance)} \end{cases} \quad (258)$$

3470 In this zero-calibration formulation,

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)}, \quad (259)$$

3471 where $N_{\text{geom}} = 8\pi^4(1 - \zeta)$ is the effective geometric stiffness and ζ is the BCC packing impedance.

3472 31.2 The Unitary Geometric Path

3473 As illustrated in the schematic, ϵ_M acts as the **Universal Gear Ratio** of the vacuum lattice.
3474 A single modulator simultaneously determines:

- 3475 • the gravitational coupling G ,
- 3476 • the electromagnetic coupling α_{geom} ,
- 3477 • the damping of the magnetic precession across generations, yielding a_e, a_μ, a_τ .

3478 This flowchart confirms that the Enhanced EWT Model is not a collection of independent
3479 equations, but a **Unitary Geometric Circuit**. Any change in the value of ϵ_M would simulta-
3480 neously shift all fundamental constants derived from it.

3481 31.3 The Geometry of the Constituent: From Cubic Grids to Spherical 3482 Units

3483 While the initial formalization of the EWT lattice utilizes the Body-Centered Cubic framework
3484 for its nodal efficiency, the physical reality of the **Elastic Medium Constituent** is fundamen-
3485 tally spherical. This transition from a “cubic cell” to a “spherical grain” is a natural consequence
3486 of the model’s convergence toward a minimum energy state and isotropic wave propagation.

3487 Packing Fraction and the Vacuum Void

3488 In a BCC lattice composed of hard spherical constituents, the maximum packing factor is

$$\eta_{\text{BCC}} = \frac{\sqrt{3}\pi}{8} \approx 0.680. \quad (260)$$

3489 This inherent geometric property implies that:

- 3490 • The vacuum is not a continuous “solid block” but a structured, granular medium with a
3491 defined interstitial capacity.
- 3492 • The volume deficit N_ν identified in the gravitational derivation represents the displacement
3493 of these spherical units.
- 3494 • The spherical nature of the EMC ensures isotropic nodal stiffness.

3495 The Transition of Density Levels

3496 The granular nature of the EMC directly dictates the three levels of vacuum density identified
3497 in the EWT hierarchy:

- 3498 • **Maximum packing:** $N_{\nu,\max} \approx 5.30 \times 10^{54}$.
- 3499 • **Statutory background:** $N_{\nu,\text{stat}} \approx 3.30 \times 10^{52}$.
- 3500 • **Effective gravitational density:** $N_{\nu,\text{eff}} \approx 6.25 \times 10^{48}$.

3501 31.4 Pillar 1: The N_ν Deficit and Soliton Stability

3502 A cornerstone of the EWT model is the derivation of the gravitational constant G from the
3503 microscopic geometry of the neutrino soliton and the electron soliton. In the zero-calibration
3504 formulation, the transition from the statutory background to the effective density is governed by
3505 the geometric dilution factor X_{eff} :

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (261)$$

3506 where X_{eff} is fixed by A_π , $K_{WC} = 10$, and the ideal BCC projection factor $L_p^{\text{geom}} = 2/\sqrt{3}$.
3507 The resulting density hierarchy is:

$$\rho_{\text{eff}} < \rho_{\text{stat}} < \rho_{\max}. \quad (262)$$

3508 Macroscopic gravitational attraction is the response of the external, higher-density vacuum
3509 medium ($N_{\nu,\text{stat}}$) attempting to restore equilibrium by pressing toward the lower-density soliton
3510 core.

3511 31.5 Pillar 2: The Dynamic Scaling Operator Ω_{Push}

3512 The dynamic push-out operator,

$$\Omega_{\text{Push}} \equiv G_{\text{Base}} \cdot A_\pi^{-1} \cdot (N_{\text{geom}} A_\pi)^{-3}, \quad (263)$$

3513 is the central mechanism in the G equation.

3514 The final gravitational identity is:

$$G \equiv \underbrace{G_{\text{Base}} \cdot \frac{1}{A_\pi} \cdot \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3}_{\Omega_{\text{Push}}} \cdot \underbrace{\frac{1}{K_{WC} \sqrt{N_{\nu,\text{eff}}}}}_{T_{\text{Surface}}}. \quad (264)$$

3515 The factor $\epsilon_M = (N_{\text{geom}} \pi^3)^{-1}$ is the master key of this operator. It dictates both the
3516 gravitational scale and the lepton anomalous magnetic moments.

3517 31.6 Pillar 3: The Recursive Paradigm — Hierarchical Nodal Integra- 3518 tion

3519 The transition from the electron core to the muon and tau generations is viewed as a hierarchical
3520 integration of nested nodal shells, anchored by the Fibonacci invariants

$$L_\mu = 5, \quad L_\tau = 34. \quad (265)$$

3521 The full AMM predictions are:

$$3522 \quad a_e^{\text{EWT}} = 1.159916 \times 10^{-3}, \quad a_\mu^{\text{EWT}} = 1.166213 \times 10^{-3}, \quad a_\tau^{\text{EWT}} = 1.176838 \times 10^{-3}. \quad (266)$$

3523 The recursive architecture replaces the perturbative loop paradigm of the Standard Model
3524 with a single unified geometric identity.

3524 31.7 The Soliton Radius and Neutrino Interaction Cross-Section

3525 A common concern regarding geometric particle models is the apparent tension between a com-
3526 paratively large geometric radius and the extremely small neutrino interaction cross-sections.
3527 This model resolves the issue by distinguishing between:

- 3528 • the **geometric soliton radius** r_{geom} ,
- 3529 • the **interaction cross-section** σ_ν .

3530 The weakness of the neutrino interaction reflects the fact that only a minute fraction of
3531 the soliton's internal energy is available at its boundary for weak interactions. This dilution is
3532 quantified by the effective volume deficit:

$$\sigma_\nu \propto \frac{1}{N_{\nu, \text{eff}}}, \quad (267)$$

3533 so that even a soliton with a substantial geometric radius can possess an exceedingly small
3534 interaction cross-section.

3535 31.8 Paradigm Shift: The Planck Length as a Physical Boundary

3536 In EWT, the Planck length is assigned a definitive physical and geometric role: it is the approx-
3537 imate magnitude of the base quantum distance λ_l , which defines the physical separation of the
3538 Elastic Medium Constituents.

3539 In this framework, λ_l is not an external input; it is the self-consistent geometric Planck length
3540 derived in Section 11.6. All physics operates consistently at and above this scale, allowing the
3541 direct geometric calculation of macroscopic constants like G and α .

3542 31.9 The ϵ_M Factor: Universal Geometric Modulator

3543 The core tenet of EWT is that mass, charge, and spin are manifestations of the Soliton's wave
3544 geometry. The unified role of the magnetic deficit factor is governed by a fundamental geometric
3545 duality: while the Soliton's internal energy storage follows $E \propto r^5$, the volume of the displaced
3546 elastic medium follows $V \propto r^3$.

3547 The factor ϵ_M acts as the universal modulator that reconciles these two scaling laws. It
3548 performs three distinct functions:

- 3549 1. **Gravity:** It scales the volumetric deficit to the observed gravitational constant G .
- 3550 2. **Electromagnetism:** It bridges the gap between α_{geom} and the soliton core.
- 3551 3. **Spin/AMM:** It defines the recursive nodal integration of lepton anomalies.

3552 The necessity of using the same factor ϵ_M across all these domains is the definitive proof of
3553 geometric unification.

31.10 Geometric Self-Consistency of the Planck–Gravity–Metric Triangle

A central result of the present work is the recognition that G_{geom} , $\hbar_{\text{geom}}$, λ_l , and c do not form a hierarchy of independent constants. They are linked by the closed geometric condition

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}, \quad (268)$$

where

$$\hbar_{\text{geom}} = \frac{m_e c r_e}{\alpha_{\text{geom}}}, \quad G_{\text{geom}} = \frac{G_{\text{Base}}}{A_\pi} \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}}. \quad (269)$$

The effective density $N_{\nu, \text{eff}}$ itself depends on λ_l through the statutory background,

$$N_{\nu, \text{eff}} = \frac{1}{X_{\text{eff}}} \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (270)$$

Thus Eq. (268) is not a definition imported from outside the model. It is an internal algebraic constraint that simultaneously fixes the gravitational scale, the quantum scale, and the fundamental lattice spacing from the same BCC geometry.

In natural units ($c = 1$), this constraint reduces to the purely geometric statement

$$\lambda_l^2 = \hbar_{\text{geom}} G_{\text{geom}}, \quad (271)$$

showing that the square of the fundamental EMC length is the product of the geometric quantum of action and the geometric gravitational coupling.

This closure is a direct consequence of the BCC lattice structure. It is not an import from the Standard Model: the Planck scale, the reduced Planck constant, and the gravitational constant are reconstructed here as derived quantities, not assumed inputs.

31.11 Final Synthesis

The Enhanced EWT model demonstrates that the fundamental constants are integrated resonances of a single BCC substrate. The geometric vacuum stiffness N_{geom} , the magnetic deficit ϵ_M , and the geometric core A_π together determine the fine-structure constant, the gravitational constant, the lepton anomalous magnetic moments, and the principal atomic scales.

The model is not claimed to be absolutely parameter-free. It currently uses four experimental anchors:

$$r_e, \quad m_e, \quad c, \quad e. \quad (272)$$

These anchors are fixed by measurement and by the metric convention. They are not adjustable calibration parameters: if any one of them were changed independently while keeping the BCC geometry fixed, the entire set of geometric predictions would break. The model therefore contains no free calibration constants; it is zero-free-parameter in the operational sense.

Of these anchors, c is a metric conversion factor rather than a dynamical parameter. The electron mass m_e may also be derivable in the future through the $E \propto r^5$ scaling law and the $K_{WC} = 10$ stability condition. The true irreducible anchors would then reduce to r_e and e , electromagnetism, and the lepton hierarchy.

A.1 List of Model Parameters and Physical Constants

35 86

35 87

35 88

35 89

The following table lists the fundamental physical constants and key dimensionless geometric factors used in the Geometric Soliton Model. The numerical consistency of the model relies on the exact values shown below, combining CODATA 2022 constants with the derived EWT geometric parameters.

Table 18: **EWT Parameters and CODATA 2022 Values Used in the Geometric Derivations**

Parameter	Symbol	Numerical Value	Source / Justification
I. Fundamental Constants (CODATA 2022)			
Speed of Light	c	299792458	Defined constant (m/s).
Electron Mass	m_e	$9.1093837015 \times 10^{-31}$	CODATA 2022 reference (kg).
Classical Radius	r_e	$2.8179403262 \times 10^{-15}$	CODATA 2022 reference (m).
II. Hierarchical Volume Deficit Parameters			
Absolute Maximum	$N_{\nu,\max}$	5.3004×10^{54}	Theoretical EMC packing limit.
Statutory Background	$N_{\nu,\text{stat}}$	3.2986×10^{52}	Eulerian vacuum capacity.
Effective Deficit	$N_{\nu,\text{eff}}$	6.2472×10^{48}	Integrated Soliton density.
Geometric Bridge Operator	X_{eff}	5275.7683	Transforms $N_{\nu,\text{stat}}$ into $N_{\nu,\text{eff}}$.
III. Geometric Operators			
Geometric Base	A_π	137.0363037759	$4\pi^3 + \pi^2 + \pi$. Static foundation.
Effective Stiffness	N_{geom}	778.8025179	$8\pi^4(1 - \zeta)$.
Lattice Impedance	ζ	0.0006033964	From BCC packing fraction.
Magnetic Deficit	ϵ_M	$4.141169769 \times 10^{-5}$	$1/(N_{\text{geom}}\pi^3)$.
Lattice Projection	L_p^{geom}	1.1547005384	$2/\sqrt{3}$, ideal BCC projection.
Unified Coupling	C_{unif}	1.1020116168	Using L_p^{geom} .

A.2 Computational Scripts (Python)

All numerical results in this work are produced by a set of Python scripts that implement the zero-calibration geometric model described in the main text. The scripts are self-contained and use only standard scientific libraries. The source code and console outputs are listed below. Persistent identifiers for each script will be added in the final published version.

A.2.1 Emergence Engine

`ewt_emergence_engine.py` is the core geometric engine. It derives the fine-structure constant, magnetic deficit, neutrino radius, Planck length, gravitational constant, lepton anomalous magnetic moments, and atomic scales from the BCC lattice geometry. The script also performs the rigidity tests described in Section 28.

A.2.3 Extended Lepton AMM

`ewt_amm_extended.py` computes the full anomalous magnetic moments of the electron, muon, and tau using the geometric fine-structure constant and the magnetic deficit. It also reports the internal shell references and the corresponding consistency errors.

```

4995  #!/usr/bin/env python3

Listing 10: Console output from `ewt_particle_masses.py`.

A.2.11 Robustness and Stability Plots

`ewt_robustness_plots.py` generates the stability figures used in Section 28, including the G surface transition, alpha sensitivity, phase-space trajectory, point-lock convergence, and AMM robustness curves.

```

6142 #!/usr/bin/env python3
6143 """
6144 From manuscript version: 5.0.0
6145
6146 Enhanced EWT -- Robustness & Stability Plot Suite
6147 =====
6148 Python port of EWT_Robustness_G_AMM_check.sc (Modules 1-10),
6149 adapted to the zero-calibration geometric version.
6150
6151 Uses the geometric eps_M derived from BCC packing impedance
6152

```

```

6153 instead of the old calibrated N_final and L_p.
6154
6155 Generates the same PDF figures as the Scilab original.

6694 Statements and Declarations

6695 **Funding:** The author declares that no funds, grants, or other support were received during the
6696 preparation of this manuscript.

6697 **Competing Interests:** The author has no relevant financial or non-financial interests to
6698 disclose.

6699 **Author Contributions:** Ł. Smoliński is the sole author of this manuscript, responsible for
6700 the conceptualization, methodology, formal analysis, and writing.

6701 **Data and Code Availability:** The complete repository for Project MagnetismGravity is
6702 openly accessible to support scientific reproducibility:

- 6703 • **Datasets:** The EWT core dataset is available on Hugging Face: <https://huggingface.co/datasets/luksmol/EWT-Vacuum-Lattice-Unified-Physics/tree/main>.
- 6705 • **Interactive Auditor:** The web-based EWT Auditor application is deployed at: <https://huggingface.co/spaces/luksmol/EWTAuditor>.
- 6707 • **Version Control:** The active development source code is maintained on GitHub: <https://github.com/lsmolinski/MagnetismGravity>.
- 6709 • **Archived Document & Core Script:** The comprehensive unifying identity document
6710 and the primary calculation script (`EWT_G_AMM_check.sc`) are archived under DOI: <https://doi.org/10.5281/zenodo.17698582>.
- 6711

- 6712 • **Robustness Analysis Script:** The Module 10 script (`EWT_Robustness_G_AMM_check.sc`)
6713 is archived under DOI: <https://doi.org/10.5281/zenodo.18469103>.
- 6714 • **Resonance Search Script:** The AMM search module (`AMM_find.sc`) is archived under
6715 DOI: <https://doi.org/10.5281/zenodo.18469206>.
- 6716 • **Standard Model Comparison Script:** The benchmark script (`EWT_VS_SM.sc`) is archived
6717 under DOI: <https://doi.org/10.5281/zenodo.17726690>.

Final Remark

The history of physics teaches us that the path to unification often lies within the most fundamental constituents of nature. Just as the quest to fully understand the electron once held the promise of unraveling quantum electrodynamics, the evidence presented in this geometric, unified model points to a more profound truth. By demonstrating that the neutrino's inherent wave geometry is the common source of the gravitational constant $\mathbf{G}$, the fine-structure constant α , and the anomalous magnetic moments, the picture is also completed by the discovery of the Weinberg and Cabibbo angles as the structural resonance limits of the vacuum lattice. The conclusion is inescapable: **It would have been enough to understand the neutrino.**
