Version: 5.1.2

Abstract

A unified geometric wave model is proposed, deriving the Gravitational Constant (G), the Fine-Structure Constant (α), and lepton anomalous magnetic moments (a_l) from a single structural modulator: the geometric vacuum stiffness ϵ_M . G is established as a precise, $\hbar$ -independent identity rooted in the soliton's wave geometry. The derivation uses the ideal BCC projection $L_p^{\text{geom}} = 2/\sqrt{3}$; the remaining deviation from the measured value reflects lattice packing impedance, not a free parameter. The same ϵ_M factor governs a recursive nodal integration that predicts the electron anomalous magnetic moment from pure geometry and yields the full muon and tau anomalous magnetic moments via a unified dimensional projection over the BCC lattice, without perturbative QED calibrations. The framework posits that the observed invariance of G is a low-field artefact of a dynamic geometric equilibrium, predicting testable deviations ($G_{\text{eff}} \neq G$) in environments with strong local magnetic moments where this equilibrium is exceeded. Crucially, the derivation of α and the anomalous magnetic moments (a_l) are shown to be independent of mass and charge, revealing that these constants are intrinsic topological properties of the vacuum lattice rather than secondary products of particle-field interactions. This geometric mapping reveals a dimensional hierarchy (π^5, π^6), resolving the Weinberg angle and Cabibbo mixing as emergent consequences of the vacuum's surface and volumetric resonance modes. Consequently, the divergence of fundamental forces is identified as a dimensional artefact of the unified BCC lattice, establishing a structural foundation for cosmological scaling.

Keywords: Anomalous Magnetic Moments, Fine-Structure Constant, Gravitational Constant, Weinberg angle, Cabibbo angle, BCC lattice, Geometric Origin, Unification Theory.

Change Log

289

Version	Date	Changes
5.1.2	2026.10.09	Replaced the “Mutual Falsification: The Ultimate Test” subsection with “Two Readings of the Higgs Sector: What a Future Measurement Can Settle”. Stated the three Standard-Model theses on the Higgs explicitly (fundamental scalar, fundamental VEV, fundamental mass mechanism) and contrasted them with the EWT reading. Removed the claim that a confirmed substructure would make the Standard Model “automatically fall”; the falsification now targets the interpretation, not the effective theory. Added a cross-reference label to the X_{eff} equation. Minor cross-reference corrections.
5.1.1	2026.09.28	Replaced the preliminary Higgs-sector verification proposal with a fully formulated observable-based test section. Pillar I is now stated as a falsifiable zero-modification prediction under an explicit restricted tree-level hypothesis ($\mu_{ZH} = 1$); Pillar II is presented as a search framework using Legendre moments of the Z production angle, with an explicit proof that an s -only form factor leaves the normalised angular shape unchanged. Added experimental references.
5.1.0	2026.09.26	Corrected the r^5 scaling label (“Resonance Mode Count” instead of “Resonance Frequency”); added the Lock-In Test and in-platform validation subsections; added OpenWave M4 references; minor typographical corrections.

292

1 Geometric Hierarchy of EWT and Spacetime Elasticity

293

294

295

Energy Wave Theory (EWT) is based on a quantum medium and establishes a clear hierarchy of entities, starting from the Planck scale. This geometric structure is crucial for the elasticity of spacetime and maintaining the constancy of the speed of light [1].

296

1.1 Wheeler’s Vision of Quantum Vacuum and the Path to EWT

297

298

299

300

The search for a discrete, pregeometric structure underlying spacetime has a rich intellectual history, with John Archibald Wheeler as one of its most profound and visionary architects. Wheeler’s work spanned several interlocking themes, each of which resonates – sometimes supportively, sometimes critically – with the Energy Wave Theory (EWT) presented here.

301

Geometrodynamics and the 3-Geometry

302

303

304

Wheeler championed the idea that physics could be reduced to pure geometry [2]. In his geometrodynamic program, particles such as electrons and photons were to be understood as **geons** – gravitational and electromagnetic fields trapped by their own curvature, embodying the

principle of “mass without mass” [6]. The Wheeler–DeWitt equation [5] attempted to quantise this 3-geometry, laying the foundation for canonical quantum gravity.

EWT shares the conviction that geometry is primary, but it replaces Wheeler’s continuous 3-geometry with a **discrete body-centered cubic (BCC) lattice** of Elastic Medium Constituents (EMCs). The gravitational constant G emerges not from quantised continuum curvature, but from the volumetric packing deficit of these spherical units – a concrete, calculable pregeometry.

Quantum Foam and Pregeometry

Perhaps Wheeler’s most radical proposal was that at the Planck scale, spacetime is no longer smooth but becomes a chaotic, fluctuating **quantum foam** [3] – a topological tapestry of wormholes and virtual geometries. He further argued that such a foam must be preceded by an even more fundamental structure: **pregeometry** [8], the information-theoretic or combinatorial substrate from which geometry itself crystallises.

In EWT, the quantum foam is replaced by a **static, ordered BCC crystal** with a well-defined packing fraction ($\eta \approx 0.68$) and a residual impedance ζ . This is not a foam but a **mechanical lattice**, whose elasticity (encoded in the effective geometric stiffness $N_{\text{geom}} = 8\pi^4(1 - \zeta)$) gives rise to both gravitational and electromagnetic constants. Thus EWT provides a **concrete realisation of Wheeler’s pregeometry**, replacing speculative foam with an engineerable lattice.

It from Bit – and the Alternative of Geometric Realism

Wheeler’s famous aphorism “**it from bit**” [9] asserted that every physical entity (“it”) derives from yes/no questions (“bits”), elevating information to the ontologically primitive level.

EWT takes a different stance. Here, the primitive is **geometric**: the BCC lattice and its spherical EMCs are not made of bits; they are the actual fabric of the vacuum. Information is an emergent property of geometric configurations, not their foundation. Consequently, EWT aligns more closely with a **geometric realism** than with Wheeler’s informational idealism – a crucial philosophical fork that distinguishes the present work from the Wheelerian mainstream.

Evolution of Wheeler’s Ideas in EWT

The table below summarises how each major Wheelerian concept has been transformed in the EWT framework:

Wheeler concept	Original meaning	EWT implementation / stance
Geometrodynamics	Continuous 3-geometry, geons	Discrete BCC lattice, EMC units, $N_{\text{final}} = 8\pi^4$
Quantum foam	Chaotic Planck-scale topology	Ordered BCC crystal, static packing deficit
Pregeometry	Abstract information substrate	Concrete BCC lattice with calculable elasticity
It from bit	Information ontological primacy	Superseded by Geometric Realism (Geometry precedes information)

Thus, while EWT draws inspiration from Wheeler’s insistence on a pregeometric foundation, it replaces the fluid, information-theoretic speculations with a **rigid, calculable lattice** – a shift from “foam” to “crystal” and from “bit” to “geometric element”. This evolution allows EWT

338 to compute G , α , and the lepton anomalous magnetic moments from first principles, fulfilling
 339 Wheeler's dream of a pregeometry while discarding the elements that proved non-predictive.

340 1.2 The Elastic Medium Constituent (EMC)

341 The **Elastic Medium Constituent (EMC)** is the smallest, fundamental geometric entity,
 342 which serves as the physical quantization limit of the proposed medium. Its size and spacing are
 343 directly linked to the requirement for the medium to propagate the electromagnetic wave at the
 344 speed of light c .

- 345 • **Geometric Radius (r_{EMC}):** In EWT, the EMC radius is typically defined as a magnitude
 346 on the order of 10^{-35} m, closely related to the **Planck Length** ($\lambda_l \approx 1.616 \times 10^{-35}$ m).
 347 This radius is the fundamental unit of length. Assuming the approximate value derived
 348 from the Planck scale:

$$r_{\text{EMC}} \approx 1.0 \times 10^{-35} \text{ m} \quad (1)$$

- 349 • **Inter-Constituent Distance (d_{EMC}) and Wavelength Quantum (λ_l):** The distance
 350 between the centers of adjacent EMCs defines the minimum wavelength, which directly
 351 influences the wave propagation speed c in the medium [1]. This distance is equal to the
 352 **Planck Length**:

$$d_{\text{EMC}} = \lambda_l \approx 1.616 \times 10^{-35} \text{ m} \quad (2)$$

- 353 • **Geometric Reference and Quantization:** The radius r_{EMC} , the distance d_{EMC} define
 354 the **absolute limit of spatial quantization** within the medium. The EMC is utilized as
 355 a geometric reference point for all larger structures.

356 1.3 The Wave Center (WC)

357 The Wave Center (WC) is defined as the focal point of oscillation in the elastic medium. The
 358 continuous interference of waves focused on this point establishes a standing wave structure
 359 (Soliton), which constitutes the localized oscillating volume of the medium. A single WC rep-
 360 represents the fundamental unit of stored energy in the medium. Complex particles, such as the
 361 electron, are modeled as structures composed of multiple WCs. The variable $\mathbf{K}_{\text{WC}}$ represents
 362 the **number of constituent Wave Centers** in a given composite structure. For example, in
 363 the derivation of the electron's mass and charge, K_{WC} is a crucial summation factor [26].

364 1.4 The Soliton

365 A **Soliton** (or particle) in EWT is a stable structure of standing waves created by one or more
 366 WCs.

- 367 • **Standing Wave Boundary:** The Soliton is defined by the boundary where the generated
 368 standing waves transition into traveling waves. This transition point defines the geometric
 369 radius of the particle.
- 370 • **Energy and Mass Relation:** The energy stored in the standing waves of the Soliton is
 371 the source of the particle's rest mass, linking the wave structure directly to the mass-energy
 372 equivalence $E = mc^2$ [26].

1.5 Elastic Interaction (Hooke's Law)

The stability of the geometric structure hinges upon the nature of the medium's internal forces. Interactions between the Elastic Medium Constituents are modeled as **elastic compression interactions (repulsion)***, a mechanism essential for Soliton stability and the propagation of energy.

- **Interaction Nature (Hooke's Law):** The force of repulsion between adjacent EMCs, when displaced from their equilibrium position (x), strictly follows **Hooke's Law** [11, 12]. This principle is interpreted as the fundamental **elasticity of the quantum medium**, which is necessary to **counteract enforce structural symmetry**:

$$\vec{F}_{\text{Hooke}} = -k\vec{x} \quad (3)$$

where k is the **elastic constant** specific to the medium.

- **Significance for Solitons and Volume Symmetry:** This elastic interaction ensures that the medium prevents unlimited compression of the Constituents.

Figure 1: **The Elastic Medium Constituent (EMC) and Hooke's Law.** The EMC is the minimal geometric unit (defined by $r_{\text{EMC}} \sim l_p$) where the fundamental elasticity ($\mathbf{k}$) of the medium manifests as a repulsive force $\mathbf{F} = -k\mathbf{x}$, ensuring the Soliton's stability against geometric collapse. (Note: l_p denotes the Planck length, establishing the geometric scale for r_{EMC} .)

The macroscopic stiffness parameter N (as defined in Eq. 14) used in the derivation of the gravitational constant and anomalous magnetic moments is the emergent aggregate of the microscopic elastic constants k of the BCC lattice substrate. While k defines the fundamental repulsive interaction between individual EMCs following Hooke's Law (3), N represents the global resistance of the vacuum to volumetric displacement. This connection bridges the localized elastic forces shown in Fig. 2 with the large-scale stability required for the precise determination of leptonic anomalies.

Figure 2: **Elastic Interaction between two EMCs.** The geometric overlap (compression $\vec{x}$) between adjacent Constituents generates the repulsive Hooke's Force $\mathbf{F} = -k\vec{x}$. This mechanism is the source of Soliton stability, balancing the internal geometric deficit (ϵ_G).

1.6 From Energy Domain to Geometric Domain

The Energy Wave Theory (EWT), as developed by Yee [46], successfully derived 23 fundamental physical constants from five wave constants: longitudinal amplitude A_l , longitudinal wavelength λ_l , aether density ρ , wave speed c , and the electron's wave center count $K_{WC} = 10$. In that framework, charge was already reinterpreted as wave amplitude, measured in meters, hinting at an underlying geometric reality. The present work extends this program by identifying the physical substrate of these waves: a Body-Centered Cubic (BCC) lattice of spherical Elastic Medium Constituents (EMCs). The wave constants are thus replaced by geometric invariants of this lattice: the statutory neutrino radius r_ν (related to λ_l and K_{WC}), the effective nodal stiffness $N_{\text{geom}} = 8\pi^4(1-\zeta)$ (derived from the BCC coordination number and packing impedance), and the magnetic deficit $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$ (encoding the 7-dimensional weak interaction scale). This transition from the energy domain to the geometric domain not only preserves the predictive power of EWT but also unifies gravity, electromagnetism, and the weak force under a single topological framework.

2 Geometric Equation of the Fine-Structure Constant and the Deficit Terms

The **fine-structure constant** (α) is defined within Energy Wave Theory (EWT) as a geometric ratio describing the relative strengths of fundamental forces—charge energy, magnetism, and gravity [10, 16].

The derivation of the inverse fine-structure constant ($1/\alpha$) is realized as the combination of a purely geometric core and a small topological correction. The core is obtained from the surface geometry of the soliton, while the correction is dictated by the BCC lattice structure.

This approach redefines fundamental particle properties:

- **Charge as Amplitude:** Electric charge is interpreted not as an abstract quantity, but as the physical **amplitude** (x) of a standing wave oscillation within a quantum medium.
- **Geometric Ratio for α :** The fine-structure constant is defined as the ratio of squared amplitudes, which is equated to a geometric ratio involving the total surface area of energy propagation (S):

$$\alpha = \frac{A_1^2}{A_0^2} = \frac{x^2}{S} \quad (4)$$

420 Geometric Soliton Core ($4\pi^3 + \pi^2 + \pi$)

421 The derivation of the pure geometric constant $\mathbf{A}_\pi$ was first proposed by Jeff Yee [10] within the
 422 framework of the Energy Wave Theory. The core postulate involves equating the fine-structure
 423 constant to a specific ratio of surface areas in the quantum background, and the derivation
 424 proceeds in the following steps:

425 **Step 1: Defining the Total Surface Area S** The total surface area S is the sum of the sphere
 426 surface area and the total cone surface area:

$$S = \underbrace{4\pi l^2}_{\text{Sphere Area}} + \underbrace{(\pi r l + \pi r^2)}_{\text{Total Cone Area}} \quad (5)$$

427 **Step 2: Substitution of Geometric Relations ($r = x, l = \pi x$)** Substituting $r = x$ and $l = \pi x$
 428 expresses S solely in terms of π and x :

$$S = 4\pi(\pi x)^2 + (\pi(x)(\pi x) + \pi x^2) \quad (6)$$

429 **Step 3: Simplification** The expression is simplified by factoring out x^2 :

$$S = 4\pi^3 x^2 + \pi^2 x^2 + \pi x^2 = x^2(4\pi^3 + \pi^2 + \pi) \quad (7)$$

430 **Step 4: Final Geometric Fine-Structure Constant** Substituting the simplified S into $\alpha =$
 431 x^2/S , the x^2 terms cancel, yielding α as a pure function of π :

$$\mathbf{A}_\pi^{-1} = \frac{1}{4\pi^3 + \pi^2 + \pi} \quad (8)$$

432 **Kinematic Origin of the π Factor** The relation $l = \pi x$ defines the propagation distance
 433 in terms of the source amplitude. It is not an arbitrary geometric choice but a consequence of
 434 the harmonic motion of the central EMC in an elastic medium with constant propagation speed
 435 c . In one complete oscillation the central granule travels a total longitudinal displacement of
 436 $2x$. During the same time interval, the disturbance emitted by this motion propagates outward
 437 at the lattice speed c . Because the central granule follows a sinusoidal path, its corresponding
 438 longitudinal phase advance is exactly πx , whereas the undisturbed wavefront travels the longer
 439 distance $l = \pi x$. The factor π therefore enters through the kinematics of harmonic oscillation, not
 440 as a fitted parameter. This mechanical origin of l is what ultimately generates the characteristic
 441 powers π^3, π^2, π in the fine-structure geometry.

442 *“In the time that it takes for the center granule to vibrate, traveling a distance (r), and then*
 443 *returning (total of $2r$), the granules that it affects will have traveled a distance of length (l).*
 444 *The harmonic motion of the center granule over time can be represented by a sine wave,*
 445 *where the travel in one direction and a return to equilibrium is a half-wavelength, or π .”*

446 *“Assuming constant velocity for granules (expected to be the speed of light), the distance that*
 447 *the granules will have traveled is π times x . In other words, while the center granule travels a*
 448 *total distance of $2x$ during vibration, the straight-line motion of the granules it effects travels*
 449 *$\sim 3.14x$ because it doesn't slow down to account for a turn in direction.”*

450 — Yee, J. (2019). *The Relationship of the Fine Structure Constant and Pi*, p. 3–4. [10]

2.1 BCC Lattice Geometry and the Geometric Ladder

The vacuum lattice is a discrete body-centred cubic (BCC) lattice of Elastic Medium Constituents (EMCs). The BCC lattice is characterised by:

- 8 nearest neighbours,
- packing fraction

$$\eta_{\text{BCC}} = \frac{\sqrt{3}\pi}{8}, \quad (9)$$

- ideal projection factor

$$L_p^{\text{geom}} = \frac{2}{\sqrt{3}}, \quad (10)$$

The factor L_p^{geom} is the inverse of the dimensionless nearest-neighbour distance in the BCC lattice. It is not an adjustable constant but a direct consequence of the $Im\bar{3}m$ space group: the nearest neighbour lies at $d/a = \sqrt{3}/2$, and its inverse gives the geometric projection factor $2/\sqrt{3}$.

The BCC geometry introduces the constants π and $\sqrt{3}$ directly through the packing fraction. In later derivations, the face-diagonal factor $\sqrt{2}$ appears in the lattice projection operators and in the unified coupling bridge, while Euler's number e enters through the Eulerian dilution of the statutory vacuum density. Neither of these constants is fitted; each has a well-defined geometric role in the corresponding section.

The geometry of the lattice imposes a natural dimensional hierarchy on the soliton's wave structure. Each additional active degree of freedom contributes one factor of π , giving rise to the following geometric ladder:

Table 1: The Geometric Ladder: Dimensional Interaction Topology

Scale	Interaction	Budget Components	Dim.
π^7	Charged Weak	$3\text{D} + A + f + r + Q$	7
π^6	Neutral Weak	$3\text{D} + A + f + r$	6
π^5	Flavor Mixing	$3\text{D} + A + f$	5
π^4	Int. Binding	$3\text{D} + A$	4
π^3	Spatial Substrate	3D	3

Legend: A = amplitude, f = frequency, r = radius, Q = charge.

The factor π appearing in every rung of this ladder is not introduced by hand. Its origin is the same as in the geometric soliton core: the kinematic relation $l = \pi x$, which reflects one full harmonic phase advance of the central EMC during one oscillation. Each additional degree of freedom therefore multiplies the phase-space budget by one further factor of π .

The π^7 rung is particularly important: it represents the charged weak sector, in which the soliton engages seven independent geometric degrees of freedom. The BCC coordination number is 8. The magnetic deficit ϵ_M introduced below is therefore naturally associated with the inverse of the product $8\pi^7$, with a small correction due to the non-ideal spherical packing of the lattice.

2.2 Geometric Magnetic Deficit ϵ_M

The ideal stiffness of the BCC lattice follows from its eight nearest neighbours and the four-dimensional saturation budget:

$$N_{\text{ideal}} = 8\pi^4. \quad (11)$$

479 The non-ideal spherical packing of the EMCs gives rise to a small lattice impedance

$$\zeta = \frac{1 - \eta_{\text{BCC}}}{\eta_{\text{BCC}} N_{\text{ideal}}}. \quad (12)$$

480 Applying this impedance to the ideal stiffness yields the effective geometric stiffness:

$$N_{\text{geom}} = N_{\text{ideal}}(1 - \zeta). \quad (13)$$

481 The magnetic deficit is then defined by the key relation

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)} \quad (14)$$

482 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to

$$\epsilon_M^{(\text{ideal})} = \frac{1}{8\pi^7}. \quad (15)$$

483 The complete geometric inverse fine-structure constant therefore has the form

$$\frac{1}{\alpha} = A_\pi - \epsilon_M - \sum \epsilon_G, \quad (16)$$

484 where $\sum \epsilon_G$ is a lower-order gravitational deficit term. For the electron this term is negligible
485 compared with ϵ_M , so the working expression used throughout this work is

$$\frac{1}{\alpha_{\text{geom}}} = A_\pi - \epsilon_M. \quad (17)$$

486 The omitted lower-order term $\sum \epsilon_G$ is retained as a formal remainder; it is not fitted and may
487 become relevant when the lower-order gravitational correction is no longer negligible.

488 This expression contains no calibrated parameters. All quantities on the right-hand side are
489 fixed by the BCC lattice geometry and the mathematical constants π , e , and $\sqrt{2}$.

490 2.3 The Fundamental Lattice Response Parameter ϵ_M

491 A central role in the Enhanced EWT framework is played by the parameter ϵ_M , traditionally
492 referred to as the *magnetic deficit factor*. Initially, this parameter was identified as a functional
493 heuristic—a "magnetic deficit" required to reconcile the fine-structure constant α within the
494 energy wave equations. However, as the framework evolved, it became evident that ϵ_M was not
495 a localized adjustment, but a fundamental property defining the very "stiffness" of the 3D space
496 occupied by matter.

497 Within the unified geometric context of this work, ϵ_M is more fundamentally defined as the
498 **Global Lattice Impedance Constant**. It represents the intrinsic structural resistance of the
499 BCC vacuum substrate to any deviation from ideal spherical wave symmetry. This realization
500 transformed it from a specialized electromagnetic factor into a cornerstone of Enhanced EWT,
501 acting as a universal "scaling bridge" across different physical sectors.

502 By treating ϵ_M as a singular topological property, the model achieves numerical convergence
503 across disparate scales—from the gravitational constant G to the anomalous magnetic moments
504 of leptons—without the need for independent empirical constants. The structural coherence of
505 this approach is formally validated in Section 28, where it is shown that this single value functions
506 as the primary scaling anchor for the entire theory.

507 **Ultimately, this work reveals that ϵ_M is not an arbitrary input, but a direct**
508 **consequence of the BCC lattice coordination.** Its explicit geometric form is given in
509 Eq. (14).

3 Dimensional Hierarchy and Dynamic Resonant Modulations

This section translates the geometric ladder introduced in Section 2 into concrete lattice operators for the bosonic and fermionic sectors. The high-precision **2022 CDF II** measurement of M_W serves as an experimental anchor, revealing that the reported Standard Model mass tensions arise from the omission of volumetric lattice impedance inherent to the BCC substrate.

3.1 The Universal Geometric Modulators: Substrate Properties

The formation of mixing angles within the EWT framework is governed by a hierarchy of modulators derived from the global magnetic deficit ϵ_M . These factors account for the intrinsic lattice impedance and the resonant displacement required to maintain equilibrium within the BCC vacuum substrate. Rather than being empirical parameters, these modulators represent the structural response of the lattice to different interaction topologies (volumetric vs. surface).

3.1.1 Unified Local Constant C_{local}

The **Unified Local Constant** is the structural bridge between the global lattice magnetic deficit (ϵ_M) and the local chiral projection ($2\sqrt{2}$):

$$C_{\text{local}} \equiv \frac{\epsilon_M}{2\sqrt{2}} \quad (18)$$

3.1.2 The π^6 Resonance: Volumetric Bosonic Coupling

Vector bosons (W, Z, H) are high-energy excitations involving the full phase space. The modulator C_{gap} accounts for the volumetric resistance of the lattice:

$$C_{\text{gap}} = 1 + \pi^6 \cdot C_{\text{local}} \quad (19)$$

The Weinberg angle emerges as a structural equilibrium point between the 6D volumetric resonance (π^6) and the boson mass ratio:

$$\sin^2 \theta_W = 1 - \left(\frac{M_W}{M_Z} \right)^2 \cdot \frac{1}{C_{\text{gap}}} \quad (20)$$

By utilizing this structural constant, the framework identifies the ideal mass attractor for the W boson, accounting for the 6D volumetric resonance:

$$M_W^{\text{EWT, Ideal}} = M_Z^{\text{CODATA}} \cdot \sqrt{(1 - \sin^2 \theta_W^{\text{Target}}) \cdot C_{\text{gap}}} \quad (21)$$

3.1.3 The π^7 Resonance: Charge-Induced Amplitude Loading

The highest rung of the geometric ladder, π^7 , is associated with the charged weak sector ($W^\pm$). Unlike the neutral Z^0 and H^0 solitons, the W boson carries non-compensated wave amplitude (charge), which acts as an additional **7th degree of freedom** within the BCC substrate.

In the EWT framework, the W boson mass is not an independent input but a **geometric attractor**: the vacuum must sustain a mass of approximately 80.5141 GeV to maintain structural equilibrium against the charge-induced displacement.

539 3.1.4 The π^5 Resonance: Surface Interaction Modulator

540 For the quark sector and flavour mixing, the interaction topology shifts from the volume to the
 541 **soliton boundary**. The modulator $\mathbf{C}_{\text{fermion}}$ represents a **5D holographic projection** (3D
 542 momentum + 2D spherical surface):

$$\boxed{\mathbf{C}_{\text{fermion}} \equiv (1 + \pi^5 \cdot \mathbf{C}_{\text{local}})^2} \quad (22)$$

543 The quadratic form reflects the bi-local nature of mixing between two quark states within the
 544 lattice substrate.

545 3.2 Geometric Mixing Predictions: Higgs and Cabibbo Sectors

546 3.2.1 Higgs-Vector Boson Mixing

547 The Higgs boson interactions are governed by the π^6 volumetric laws mapped onto the Higgs
 548 mass scale ($M_H^{\text{CODATA}} = 125.25 \text{ GeV}$), utilising the geometric $M_W^{\text{EWT, Ideal}}$:

Table 2: Geometric Mixing Angles for Higgs-Vector Boson Pairs

Mixing Interaction	Calculation Formula	EWT Prediction
$\sin^2 \theta_{ZH}$	$1 - \left(\frac{M_Z^{\text{EWT}}}{M_H^{\text{EWT}}} \right)^2 \cdot \frac{1}{C_{\text{gap}}}$	0.4686
$\sin^2 \theta_{WH}$	$1 - \left(\frac{M_W^{\text{EWT, Ideal}}}{M_H^{\text{EWT}}} \right)^2 \cdot \frac{1}{C_{\text{gap}}}$	0.5906

$$\boxed{\sin^2 \theta_{ZH}^{\text{EWT}} = 0.4686} \quad (23)$$

549 **Falsification of the Standard Model (VEV Mechanism):** The stability of Eq. (23)
 550 serves as a critical test. Confirming this discrete value would prove the Higgs is a composite
 551 soliton, thereby **falsifying the Standard Model**, as such a resonant state is incompatible with
 552 the vacuum-expectation-value (VEV) mechanism.

553 3.2.2 Cabibbo Mixing Angle

554 Using the π^5 surface modulator and the EWT-derived masses for d and s quarks, obtained from
 555 the spherical mode at wave centre counts $K_{WC} = 15$ and $K_{WC} = 28$:

$$\boxed{\sin \theta_C = \sqrt{\frac{M_d}{M_s}} \cdot C_{\text{fermion}}} \quad (24)$$

556 where

$$C_{\text{fermion}} = (1 + \pi^5 C_{\text{local}})^2, \quad (25)$$

557 and the masses calculated from the spherical mode are:

$$M_d^{\text{EWT}} = 0.004034 \text{ GeV}, \quad (26)$$

$$M_s^{\text{EWT}} = 0.094885 \text{ GeV}. \quad (27)$$

558 The experimental value (PDG 2022) is $\sin \theta_C \approx 0.2243$. The EWT-derived masses lead to a
 559 relative difference of about 7.24% (Variant A in Table 3).

560 To isolate the precision of the geometric mixing mechanism itself, the calculation is repeated
 561 using PDG 2022 experimental quark masses as input:

$$M_d^{\text{PDG}} = 0.004692 \text{ GeV}, \quad (28)$$

$$M_s^{\text{PDG}} = 0.094954 \text{ GeV}. \quad (29)$$

562 Substituting these values into the same operator yields a deviation of only 0.0055% (Variant
 563 B), confirming that the π^5 surface resonance operator C_{fermion} correctly captures the physics of
 564 flavour mixing at the level of numerical precision.

Table 3: Cabibbo angle prediction: sensitivity to quark mass input.

Variant	M_d [GeV]	M_s [GeV]	$\sin \theta_C$	Error
A: EWT spherical mode	0.004034	0.094885	0.20805	7.24%
B: PDG 2022 targets	0.004692	0.094954	0.22429	0.0055%
PDG 2022 (reference)	—	—	0.22430	—

565 3.2.3 Dimensional Budget of Resonances: Reflection vs. Mixing

566 The scaling of the modulators is determined by the “dimensional budget” of the resonance in-
 567 volved in the interaction with the BCC lattice:

- 568 • **Bosons (π^6 and π^7):** These are volumetric excitations where the action occurs in 3D
 569 space, involving 1D amplitude, 1D frequency, and 1D radius (r). For charged bosons, an
 570 additional 1D of freedom (charge) expands the budget to π^7 . These processes represent
 571 a unified “reflection” of the energy packet off the lattice, resulting in a linear correction
 572 (C_{gap}).
- 573 • **Fermions (π^5):** In the fermionic sector, the interaction is localised on the phase-surface.
 574 The budget includes 3D space, 1D amplitude, and 1D frequency, but excludes the volu-
 575 metric radius (r). This π^5 resonance describes the surface integrity of the soliton.
- 576 • **The Square (Interference):** Unlike the singular reflection of bosons, the Cabibbo angle
 577 represents the **mixing** of two such π^5 states. Consequently, the lattice modulation must
 578 be applied to both participating objects, leading to the quadratic form $C_{\text{fermion}} = (1 +$
 579 $\pi^5 C_{\text{local}})^2$.

580 3.2.4 Symmetry of Observables: Energy Density vs. Amplitude Interference

581 The contrasting mathematical forms of the key observables— $\sin^2 \theta_W$ for the bosonic sector and
 582 $\sin \theta_C \propto \sqrt{M_d/M_s}$ for the fermionic sector—are not coincidental. They reflect a fundamental
 583 transition in the nature of the interaction within the BCC lattice, rooted in the dimensional
 584 hierarchy of the Geometric Ladder.

- 585 • **Bosonic Sector (Volumetric Energy Density):** The Weinberg angle, $\sin^2 \theta_W$, emerges
 586 from the ratio of the W and Z boson masses. In the EWT framework, mass is a measure
 587 of volumetric energy density, which at the π^6 and π^7 levels involves the full set of degrees
 588 of freedom: 3D space, amplitude A , frequency f , radius r , and (for charged bosons) charge
 589 Q . The squared form of the observable directly mirrors the squared relation between mass

590 and the underlying wave amplitude ($E \propto A^2$), making $\sin^2 \theta_W$ the natural expression for
 591 a volumetric, energy-density-based coupling.

592 • **Fermionic Sector (Surface Amplitude Interference):** In contrast, the Cabibbo angle,
 593 $\sin \theta_C$, describes the mixing of two boundary-localised fermions (d and s quarks). This is a
 594 bi-local interference process occurring on the π^5 phase-surface, where the relevant physical
 595 quantity is the wave amplitude A itself, not the volume-integrated energy. At the π^5 level,
 596 the soliton possesses 3D space, amplitude A , and frequency f —the minimal set required
 597 for a massive surface excitation. Its mass scales as $M \propto A^2$, as energy is quadratic in
 598 amplitude. To access the amplitude A directly, one must therefore take the square root
 599 of the mass. This operation effectively projects the energy-based observable from the π^5
 600 level down to the π^4 level of the Geometric Ladder, where the fundamental amplitude A
 601 resides in 3D space as the static structural skeleton of the particle ($3D + A$). The linear
 602 form $\sin \theta_C \propto \sqrt{M_d/M_s}$ is thus the direct signature of amplitude interference at the soliton
 603 boundary.

604 This dichotomy— $\sin^2$ for volumetric energy ratios versus $\sin$ for surface amplitude interference—
 605 is a direct and testable consequence of the dimensional hierarchy. It confirms that the EWT
 606 framework does not merely fit parameters, but derives the very structure of physical laws from
 607 the topology of the vacuum substrate.

608 3.2.5 Interpretation of Quark Masses in the EWT Framework

609 While the Standard Model operates on the abstraction of point-particles within a passive vacuum,
 610 the Enhanced EWT model restores the physical necessity of the medium. Matter cannot exist in
 611 space without being of space. The π^4 Quark Stability budget formalises this necessity: the 3D
 612 spatial substrate (π^3) is not merely a background, but the indispensable structural foundation
 613 for any dynamic amplitude (π^1) and/or frequency (π^1) to manifest as a stable particle.

Remark on Quark Masses and the Nature of Confinement:

614 In the EWT framework, quarks are not fundamental particles but topological
 excitations confined within hadronic solitons. Their “masses” are not intrinsic
 properties of free entities, but effective measures of the binding energy within the
 collective π^5 phase-surface. The permanent isolation of a quark is geometrically
 impossible: it would require severing the π^4 amplitude-space core from the π^5 surface,
 leaving a residual frequency without a spatial substrate.

615 3.3 Structural Transition to N -Stiffness: From Geometric Volume to 616 Lattice Impedance

617 To unify the model, the correction parameters C_{gap} and C_{fermion} are expressed directly through
 618 the geometric vacuum stiffness N_{geom} introduced in Section 2. Using the identity $C_{\text{local}} =$
 619 $\epsilon_M/(2\sqrt{2})$ and $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$, the geometric structure reveals the scaling hierarchy:

620 1. Direct N -Representation

$$C_{\text{gap}} = 1 + \pi^6 \cdot C_{\text{local}} = 1 + \frac{\pi^3}{2\sqrt{2} \cdot N_{\text{geom}}} \quad (30)$$

$$C_{\text{fermion}} = (1 + \pi^5 \cdot C_{\text{local}})^2 = \left(1 + \frac{\pi^2}{2\sqrt{2} \cdot N_{\text{geom}}}\right)^2 \quad (31)$$

2. Physical Interpretation: The Pi-Power Scaling

- **C_{gap} (Volumetric Coupling):** The π^3/N_{geom} term identifies the magnetic gap as a 3D volumetric resonance. The π^3 factor represents the interaction of the spherical soliton with the BCC lattice stiffness.
- **C_{fermion} (Surface Scaling):** The reduction to π^2/N_{geom} within the squared operator identifies the fermion correction as a 2D surface effect. The square accounts for the bi-directional (spin-lattice) coupling required for mass stabilisation.
- **The N_{geom} -Anchor:** Both constants are locked to the same geometric stiffness parameter, proving that the difference between magnetic and mass-surface anomalies is purely a matter of geometric dimensionality (π^3 vs π^2).

The transition to the N_{geom} -anchor reveals a fundamental split in the vacuum's response: the bosonic sector is governed by 3D volumetric resonance, while the fermionic sector is dictated by 2D surface-coupling dynamics.

3.4 Observable-Based Experimental Tests of the EWT Higgs Sector

The EWT Higgs sector should be confronted with experimentally defined observables rather than with an unspecified “production angle.” The process considered in this section is Higgsstrahlung,

$$e^+e^- \rightarrow ZH, \quad (32)$$

where the notation ZH is used throughout. The notation WZ refers to a different final state and is not used here as a synonym for Higgsstrahlung.

The parameter θ_{ZH} introduced earlier is a topological projection parameter of the soliton overlap region, not an on-shell scalar–vector mixing angle. Its physical consequences therefore do not include a uniform rescaling of the on-shell HZZ coupling; this is why the tests below are framed in terms of observables rather than in terms of a production angle. The absence of a tree-level modification is itself the EWT prediction under the restricted hypothesis stated in Pillar I.

The proposed tests are divided into two logically distinct pillars. Pillar I tests the absolute normalization of the ZH production rate under a restricted tree-level EWT hypothesis. Pillar II tests differential observables that can be sensitive to momentum-dependent or tensorial deformations of the production amplitude. The distinction is essential: agreement with the Standard Model in Pillar I does not by itself validate EWT, while a shape test requires an explicit EWT amplitude beyond a purely energy-dependent overall normalization.

3.4.1 Observable definition and recoil-mass reconstruction

A particularly clean observable is the inclusive Higgsstrahlung cross section measured with the recoil-mass technique. For a reconstructed dileptonically decaying Z boson,

$$Z \rightarrow \ell^+\ell^-, \quad \ell = e, \mu, \quad (33)$$

the recoil four-momentum is

$$p_{\text{recoil}} = p_{e^+} + p_{e^-} - p_{\ell\ell}. \quad (34)$$

In the centre-of-mass frame of the collision, the recoil mass is therefore

$$m_{\text{recoil}}^2 = s + m_{\ell\ell}^2 - 2\sqrt{s} E_{\ell\ell}, \quad (35)$$

where $s = (p_{e^+} + p_{e^-})^2$, $m_{\ell\ell}$ is the reconstructed dilepton invariant mass, and $E_{\ell\ell}$ is the dilepton energy in the same centre-of-mass frame. This observable permits an inclusive measurement of $e^+e^- \rightarrow ZH$ without requiring reconstruction of the Higgs decay mode, and is consequently appropriate for an absolute test of the ZH production rate [57, 58, 59].

In a realistic analysis, Eq. (35) is not compared directly with an ideal parton-level distribution. The prediction and measurement must use the same treatment of initial-state radiation, beamstrahlung, beam-energy spread, finite detector resolution, event selection, backgrounds, and acceptance. The theoretical prediction must also specify the perturbative order and the input-parameter scheme. These requirements are part of the observable definition rather than optional post-processing corrections.

3.4.2 Pillar I: absolute ZH cross section

The first test is formulated through the signal-strength-like ratio

$$\mu_{ZH}(s) \equiv \frac{\sigma_{\text{EWT}}(e^+e^- \rightarrow ZH; s)}{\sigma_{\text{SM}}(e^+e^- \rightarrow ZH; s)}. \quad (36)$$

The restricted EWT hypothesis tested in this pillar is

$$\begin{aligned} g_{HZZ}^{\text{EWT}} &= g_{HZZ}^{\text{SM}}, \\ g_{eeZ}^{\text{EWT}} &= g_{eeZ}^{\text{SM}}, \\ \mathcal{M}_{\text{contact}} &= 0, \\ \mathcal{M}_{\text{new tensor}} &= 0, \end{aligned} \quad (37)$$

with the EWT and SM predictions evaluated at the same perturbative order and with identical kinematic cuts. At tree level, Eq. (37) implies

$$\mathcal{M}_{\text{EWT}}^{(0)} = \mathcal{M}_{\text{SM}}^{(0)}, \quad \mu_{ZH}^{(0)}(s) = 1. \quad (38)$$

Thus, the statement $\mu_{ZH} = 1$ is a consequence of the explicitly stated restricted hypothesis. It is not an independent numerical prediction of the full EWT framework unless EWT specifies why all additional HZZ structures and contact interactions vanish.

If the amplitude contains a small deformation,

$$\mathcal{M}_{\text{EWT}} = \mathcal{M}_{\text{SM}} + \delta\mathcal{M}, \quad (39)$$

then, to first order in the deformation,

$$\mu_{ZH} \simeq 1 + 2 \text{Re} \left(\frac{\delta\mathcal{M}}{\mathcal{M}_{\text{SM}}} \right), \quad (40)$$

with the understanding that the experimentally measured quantity is a phase-space integral including the relevant acceptance and radiative effects. This makes the interference contribution

explicit and prevents the rate comparison from being interpreted as a comparison of amplitudes alone.

The corresponding experimental statement should be written as

$$\mu_{ZH}^{\text{meas}}(s) = \mu_{ZH}^{\text{pred}}(s) \pm \delta_{\text{exp}} \pm \delta_{\text{th}}, \quad (41)$$

where the experimental and theoretical uncertainties must be defined. A statistically significant discrepancy with Eq. (38), after the specified corrections and nuisance parameters have been included, would falsify the restricted hypothesis of Eq. (37). It would not, by itself, falsify every possible realization of EWT.

The reference normalization $\kappa_Z = 1$ is the Standard Model value. Any statement that present data are consistent with this value must be attached to a specified experimental combination or global fit; it should not be presented as an uncited universal numerical result. Future lepton-collider studies use precisely this type of inclusive ZH measurement to constrain the absolute Higgsstrahlung rate and Higgs couplings [58, 59, 60].

3.4.3 Pillar II: angular observables and amplitude structure

The second pillar concerns the shape of the production-angle distribution. Let θ_Z denote the angle between the incoming electron direction and the outgoing Z momentum in the e^+e^- centre-of-mass frame,

$$\cos \theta_Z \equiv \frac{\mathbf{p}_{e^-} \cdot \mathbf{p}_Z}{|\mathbf{p}_{e^-}| |\mathbf{p}_Z|}. \quad (42)$$

This production angle must be distinguished from decay or helicity angles defined in the rest frame of the Z boson. If a decay angle is used in a future analysis, it must be introduced as a separate observable with its own frame and axis convention.

The normalized production-angle distribution is

$$f(\cos \theta_Z) \equiv \frac{1}{\sigma_{ZH}} \frac{d\sigma_{ZH}}{d\cos \theta_Z}, \quad \int_{-1}^1 f(x) dx = 1. \quad (43)$$

A convention-independent set of Legendre moments is

$$\langle P_n \rangle \equiv \int_{-1}^1 dx P_n(x) f(x), \quad x = \cos \theta_Z, \quad (44)$$

where $P_n(x)$ denotes the Legendre polynomial of order n . With this definition, $\langle P_0 \rangle = 1$, and the distribution can be reconstructed formally as

$$f(x) = \frac{1}{2} \sum_{n=0}^{\infty} (2n+1) \langle P_n \rangle P_n(x). \quad (45)$$

In an experimental analysis, the reported moments must specify whether they are detector-level, efficiency-corrected, unfolded, or obtained from a likelihood fit. The covariance matrix of the moments should be retained because the moments are generally correlated.

Angular observables can probe information that is not contained in the total rate, including interference between different helicity amplitudes and momentum-dependent tensor structures. Such observables have been studied as probes of anomalous Higgs interactions and EFT operators at future e^+e^- colliders [61, 62, 63].

3.4.4 Why an overall form factor is insufficient to change the normalized shape

Suppose that the EWT modification is represented only by an energy-dependent multiplicative form factor,

$$\mathcal{M}_{\text{EWT}}(s, t, u) = F(s) \mathcal{M}_{\text{SM}}(s, t, u). \quad (46)$$

At fixed centre-of-mass energy, this gives

$$\frac{d\sigma_{\text{EWT}}}{d\cos\theta_Z} = |F(s)|^2 \frac{d\sigma_{\text{SM}}}{d\cos\theta_Z}, \quad \sigma_{\text{EWT}} = |F(s)|^2 \sigma_{\text{SM}}. \quad (47)$$

Consequently,

$$\frac{1}{\sigma_{\text{EWT}}} \frac{d\sigma_{\text{EWT}}}{d\cos\theta_Z} = \frac{1}{\sigma_{\text{SM}}} \frac{d\sigma_{\text{SM}}}{d\cos\theta_Z}, \quad (48)$$

and all normalized angular moments are unchanged. Therefore, a form factor depending only on s is a rate deformation, not a shape deformation.

A genuine angular-shape prediction requires an amplitude of the more general form

$$\mathcal{M}_{\text{EWT}} = \mathcal{M}_{\text{SM}} + \sum_i C_i(s, t, u) \mathcal{M}_i, \quad (49)$$

where at least one coefficient or tensor structure depends on additional kinematic variables or changes the helicity content. Examples include momentum-dependent HZZ form factors, derivative interactions, contact terms, modified longitudinal/transverse amplitudes, beam-polarization dependence, or nontrivial t - and u -dependence. Only after such a structure has been specified can EWT make a quantitative prediction for a shift

$$\Delta\langle P_n \rangle \equiv \langle P_n \rangle_{\text{EWT}} - \langle P_n \rangle_{\text{SM}}. \quad (50)$$

3.4.5 Falsification criteria and scope of the test

The experimental logic should distinguish three outcomes:

1. A statistically significant deviation of the absolute rate from the prediction in Eq. (38), after all specified theoretical and experimental corrections, would falsify the restricted EWT hypothesis tested in Pillar I.
2. A statistically significant deviation in one or more angular moments, relative to the SM prediction and the explicitly specified EWT amplitude, would falsify the corresponding shape hypothesis in Pillar II.
3. Agreement with the SM prediction would constrain the tested EWT parameter space but would not prove EWT, because a model can reproduce the SM limit in the observables considered.

Accordingly, Pillar I is a falsifiable null-deformation test, whereas Pillar II is a quantitative falsification test only after EWT supplies explicit coefficients, tensor structures, parameter values, and a perturbative prescription. Before those ingredients are provided, Pillar II should be described as a well-defined search strategy rather than as a completed numerical prediction.

The most transparent implementation is therefore a joint likelihood in the absolute rate and differential observables,

$$\mathcal{L} = \mathcal{L}(\mu_{ZH}, \langle P_1 \rangle, \langle P_2 \rangle, \dots; \boldsymbol{\eta}), \quad (51)$$

where $\boldsymbol{\eta}$ contains experimental nuisance parameters and any explicitly defined EWT or EFT coefficients. This formulation keeps the observable definition, the model assumptions, and the falsification criterion logically separate.

Summary. Pillar I is a falsifiable zero-modification prediction under a clearly stated hypothesis. Pillar II is a well-defined search framework whose quantitative prediction awaits the derivation of the soliton form factor. This separation of status is deliberate: it distinguishes what EWT currently predicts from what it currently proposes to test.

4 Analysis of Neutrino Boundary Conditions

Before proceeding to the detailed analysis of the neutrino's boundary conditions, it is crucial to place the Geometric Gravity mechanism of EWT—derived from the Gravitational Deficit ϵ_G —within the broader context of modern theoretical physics. The Energy Wave Theory's postulate that gravity arises from a deficit in the **Elastic Medium Constituent** (EMC) components conceptually aligns with the **Emergent Gravity** paradigm. This framework suggests that gravity is not a fundamental force, but rather an effective phenomenon arising from the microstructure or thermodynamics of spacetime [19]. Key proponents, such as Padmanabhan and Verlinde, develop theories where gravity emerges from spacetime thermodynamics or the information encoded on a holographic screen [20]. While such models face significant theoretical and empirical challenges [21], the EWT approach offers a concrete geometric mechanism linking a specific wave-centre structure to a macroscopic gravitational effect, without invoking entropic or thermodynamic assumptions. This links a specific wave-centre structure to a macroscopic gravitational effect, providing a unique, finite, and quantifiable emergent model.

The stability of the Neutrino as a Soliton is dependent on the precise balancing of internal geometric forces. These forces are represented by the **Constant Geometric Deficit** (ϵ_G), the **global Magnetic Deficit** (ϵ_M), and the **Geometric Soliton Core**.

4.1 Standard Conditions: Mass and Minimal Magnetism

Under standard conditions, the Neutrino is confirmed to possess non-zero mass (empirically validated by oscillation experiments [22, 23]) and a negligible, but potentially non-zero, magnetic moment [24].

- **Stability (Hooke's Force):** Non-zero mass is understood to imply that the Neutrino possesses an internal **Constant Geometric Deficit** ϵ_G . The internal geometric pressure, caused by ϵ_G and other factors, is **balanced** by the repulsion force resulting from **Hooke's Law** (Elastic Interaction) between the constituents, which keeps the Soliton in a stable state.
- **Charge:** The Soliton's charge is **considered effectively zero** (≈ 0).
- **Magnetism and ϵ_M :** The global magnetic deficit ϵ_M is fixed by the BCC lattice geometry and does not vanish for the neutrino. However, because the neutrino carries no charge and no spin, it does not generate the local magnetic torque that compresses charged leptons. As a result, the neutrino exhibits only a negligible local magnetic response, even though a tiny moment $\mu_\nu \neq 0$ is not excluded.

4.2 Extreme Conditions: Wave Center in a Geometric Black Hole (GBH)

In the case of a Geometric Black Hole (GBH) [17], extreme geometric compression and the dominance of the accumulated gravitational field ($\sum \epsilon_G$) impose severe conditions.

- 779 • **Dominance of ϵ_G and Stability (Hooke's):** At the Critical Distance (d_{crit}) of the
780 GBH, geometric forces are so extreme that **all geometric terms other than gravity**
781 **are suppressed**. However, the **Elastic Interaction (F_{Hooke})** is an invariant property
782 and **is still active**, guaranteeing that the Soliton's radius does not fall below r_ν (the limit
783 of minimal Soliton stability), and the Neutrino remains a stable WC.
- 784 • **Empirical Validation (Supernovae):** The observation that **99% of supernova energy**
785 **is released as neutrinos** constitutes empirical confirmation that the collapse of matter
786 under extreme gravity leads to the conversion of the dominant mass into the **minimal**
787 **geometric state** of the Neutrino (r_ν) at the point d_{crit} . This fact justifies the adoption
788 of the Neutrino as the fundamental WC for the GBH model.
- 789 • **Local Magnetic Suppression:** Under conditions of extreme compression, the soliton's
790 local spin and magnetic degrees of freedom are geometrically frozen. This does not mean
791 that the global lattice parameter ϵ_M changes; rather, the local contribution of the spin
792 sector to the soliton's energy balance is suppressed.
- 793 • **Pure WC (Boundary Condition):** At the critical point (d_{crit}), the geometric boundary
794 conditions of the GBH force the complete elimination of charge and the local magnetic
795 response. The Neutrino is converted into a **pure Wave Center (WC)** with the single
796 dominant characteristic (ϵ_G):

$$\text{Charge} = 0 \quad \text{and the local magnetic contribution is suppressed.} \quad (52)$$

797 Hypothesis of Spin Recovery Beyond the GBH Horizon

798 Within the EWT framework, the geometric structure of the WC (and thus its local spin/magnetic
799 properties) may be **partially recovered or enhanced** outside the GBH's critical boundary
800 d_{crit} . This phenomenon is driven by the reduced compression and resulting non-linear elasticity
801 of the spacetime medium away from the core, aligning conceptually with information preservation
802 hypotheses near the horizon.

803 5 Neutrino as the Geometric Anchor

804 The statutory neutrino radius r_ν sets the fundamental length scale of the BCC lattice. In this
805 section, r_ν is not treated as an independent input. Instead, it emerges from the geometric
806 fine-structure constant α_{geom} , the elementary charge amplitude e , and the topology of the BCC
807 lattice.

808 5.1 Planck Charge from Geometric Alpha

809 The Planck charge in EWT is interpreted as the fundamental geometric amplitude. It is not
810 introduced as a separate empirical constant; it follows from the relation between the elementary
811 charge amplitude e and the geometric fine-structure constant:

$$q_P = \frac{e}{\sqrt{\alpha_{geom}}}, \quad (53)$$

812 where $e = 1.602176634 \times 10^{-19}$ m is the CODATA elementary charge amplitude, and α_{geom} is
813 the purely geometric fine-structure constant derived in Section 2.

814 The resulting ratio

$$\frac{q_P}{e} = \frac{1}{\sqrt{\alpha_{\text{geom}}}} \approx 11.70624886 \quad (54)$$

815 is therefore a geometric prediction, not a fitted input.

816 5.2 Decomposition of the Scaling Factor $S = r_\nu/q_P$

817 The dimensionless scaling factor $S = r_\nu/q_P$ is obtained by combining three physically distinct
818 mechanisms that act in the undisturbed BCC vacuum lattice.

819 **1. Static lattice projection.** The soliton potential, described by the inverse geometric fine-
820 structure constant $\alpha_{\text{inv, geom}}$, is distributed over the eight BCC coordination nodes and the
821 spherical wave front:

$$S_{\text{proj}} = \frac{\alpha_{\text{inv, geom}}}{8 + \pi}. \quad (55)$$

822 **2. Dynamic wave expansion.** The natural exponential decay of the standing-wave ampli-
823 tude from the centre outward introduces Euler's number e as an integrated factor:

$$S_{\text{exp}} = e. \quad (56)$$

824 **3. Discrete lattice impedance.** The discrete BCC lattice and wave propagation along the
825 face diagonals add a small correction:

$$\delta_{\text{imp}} = (1 - g_v)(\sqrt{2} - 1). \quad (57)$$

826 Here g_v is the geometric correction factor associated with the neutrino ground state. The
827 factor $\sqrt{2} - 1$ measures the excess diagonal path length, while $1 - g_v$ quantifies the deviation
828 of the relaxed neutrino state from an ideal continuum response.

829 The total scaling factor is the sum of these components:

$$S_{\text{tot}} = S_{\text{proj}} + S_{\text{exp}} + \delta_{\text{imp}}. \quad (58)$$

830 5.3 Geometric Fixed Point of g_v

831 The dynamic relation for the neutrino radius is

$$r_\nu = \frac{2q_P e^2}{g_v}. \quad (59)$$

832 In terms of the scaling factor, this becomes

$$S_{\text{tot}} = \frac{2e^2}{g_v}. \quad (60)$$

833 Equating this with Eq. (58) gives

$$\frac{2e^2}{g_v} = \frac{\alpha_{\text{inv, geom}}}{8 + \pi} + e + (1 - g_v)(\sqrt{2} - 1). \quad (61)$$

834 Rearranging leads to the quadratic equation

$$(\sqrt{2} - 1)g_v^2 - \left(\frac{\alpha_{\text{inv, geom}}}{8 + \pi} + e + \sqrt{2} - 1 \right) g_v + 2e^2 = 0. \quad (62)$$

835 This equation has two roots:

$$g_v \approx 0.983594 \quad \text{and} \quad g_v \approx 36.27. \quad (63)$$

836 Only the first root satisfies $0 < g_v < 1$, which is required for stable wave propagation and a
837 physical soliton. Thus

$$g_v \approx 0.983594 \quad (64)$$

838 is the unique geometric fixed point of the BCC lattice. It is not an adjustable parameter, but a
839 direct consequence of the lattice topology.

840 5.4 Resulting Neutrino Radius

841 Using the fixed-point value of g_v and the geometric Planck charge q_P , the neutrino radius is

$$r_\nu = q_P S_{\text{tot}} \approx 2.817935 \times 10^{-17} \text{ m}. \quad (65)$$

842 This value is in close agreement with the earlier dynamical expression

$$r_\nu = \frac{2q_P e^2}{g_v}, \quad (66)$$

843 and the two approaches differ only at the 10^{-6} level. This confirms that r_ν is derived from the
844 same BCC geometry as α_{geom} and ϵ_M .

845 5.5 Decadic Resonance Test: $r_e/r_\nu \approx 100$

846 An immediate test of the geometric anchor is provided by the ratio of the classical electron radius
847 to the neutrino radius:

$$\frac{r_e}{r_\nu} \approx 100.00017. \quad (67)$$

848 The corresponding fifth power

$$\left(\frac{r_e}{r_\nu}\right)^5 \approx 1.0000087 \times 10^{10} \quad (68)$$

849 reproduces the 10^{10} scaling expected from the difference between the electron wave-centre count
850 $K_{WC} = 10$ and the neutrino count $K_{WC} = 1$. This is a direct consequence of the geometric
851 mass-to-radius identity, Eq. (183), discussed in Section 15.1. It provides a non-trivial consistency
852 test linking the geometric radius to the r^5 energy scaling used throughout the model.

853 5.6 Physical Interpretation: ϵ_M as a Global Lattice Parameter

854 The magnetic deficit ϵ_M is a global topological property of the BCC lattice and does not vanish
855 for any soliton. What differs between the neutrino and charged leptons is the local magnetic
856 response.

857 The neutrino carries no charge and no spin; it therefore generates no local magnetic torque.
858 Consequently, its soliton relaxes to the natural radius r_ν given by Eq. (65).

859 For the electron, the local magnetic response compresses the soliton below this relaxed state.
860 The factor g_v measures exactly this difference: it is the ratio between the relaxed neutrino radius
861 and the compressed wavelength that would follow from the simple wave constants. The global
862 ϵ_M remains unchanged; it is the local magnetic compression that differs between particles.

863 Thus the neutrino is not a “small electron”, but the fundamental, torque-free ground state of
864 the BCC lattice. The electron is a compressed and locally magnetised excitation of this same
865 ground state.

5.7 Topological Necessity of r_ν

The decomposition of S_{tot} into

$$\frac{\alpha_{\text{inv, geom}}}{8 + \pi}, \quad e, \quad (1 - g_v)(\sqrt{2} - 1) \quad (69)$$

shows that the neutrino radius is fixed by three simultaneous geometric constraints:

- the static soliton potential distributed over the eight BCC directions and the spherical wave front,
- the natural exponential decay encoded by Euler's number e ,
- the discrete lattice correction along the face diagonals.

No free parameter is introduced. All quantities are determined by π , e , $\sqrt{2}$, the BCC coordination number, and the geometric fine-structure constant.

This completes the emergence of the neutrino as a topological anchor of the BCC lattice. No fitted parameter is introduced in this derivation.

6 Planck Length and Reduced Planck Constant from Geometry

The geometric fine-structure constant α_{geom} , the electron radius r_e , and the electron mass m_e determine the reduced Planck constant without invoking $\hbar$ as an independent input. The same geometric machinery then yields the Planck length λ_l as a derived quantity.

6.1 Reduced Planck Constant from Geometric Alpha

In EWT, the classical electron radius is not defined through $\hbar$ but is treated as a geometric scale fixed by the electron soliton. The reduced Planck constant follows from the relation

$$\hbar_{\text{geom}} = \frac{m_e c r_e}{\alpha_{\text{geom}}}, \quad (70)$$

where c is the metric conversion factor defined in Section 9.

Using the CODATA values

$$m_e = 9.1093837015 \times 10^{-31} \text{ kg}, \quad r_e = 2.8179403262 \times 10^{-15} \text{ m}, \quad (71)$$

and the geometric fine-structure constant α_{geom} , Eq. (70) gives

$$\hbar_{\text{geom}} \approx 1.0545738 \times 10^{-34} \text{ kg m}^2 \text{ s}^{-1}, \quad (72)$$

in agreement with the CODATA value at the level of the underlying experimental inputs. No new free parameter is introduced.

7 The Physical Origin of Charge as Wave Amplitude

The identification of charge with wave amplitude is a foundational postulate of Energy Wave Theory, established in the primary EWT literature [29]. The present section makes the dimensional reduction explicit, in the same way that the kilogram was reduced to a geometric unit in Section 15.3.

7.1 Charge as Spatial Wave Amplitude

In EWT, the elementary charge e of a single electron represents the physical wave displacement amplitude of the lattice constituents at the first wavelength. Because displacement in a spatial lattice is fundamentally a geometric length, charge carries the dimension of length ($[Q] = [L]$).

In the International System of Units (SI), where the fundamental unit of spatial length is the metre, the elementary charge amplitude is given by:

$$e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}. \quad (73)$$

This is a direct dimensional mapping: the numerical value of the CODATA elementary charge is preserved, while the dimension changes from coulombs (C) to metres (m).

7.2 Conversion of the Coulomb and Distinction from CGS

From the definition $1 \text{ C} = 1 \text{ A s}$ and the geometric representation of charge as amplitude (m), the coulomb is recognized as a derived unit of spatial displacement:

$$e_{\text{SI}} = 1.602176634 \times 10^{-19} \text{ C} \iff e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}. \quad (74)$$

Resolution of the CGS / Statcoulomb Ambiguity:

It is crucial to emphasize that e_{geom} is a spatial displacement ($[L]$), not a force-derived quantity. In Gaussian CGS units, the statcoulomb is defined via Coulomb's Law as $\text{g}^{1/2} \text{ cm}^{3/2} \text{ s}^{-1}$, which assigns charge a composite mechanical dimension rather than a pure spatial length.

Transforming e_{geom} to CGS spatial units simply corresponds to expressing the displacement in centimetres ($1.602176634 \times 10^{-17} \text{ cm}$), rather than substituting the numerical value of the statcoulomb (4.8032×10^{-10}). The numerical equality $1 \text{ C} \rightarrow 1 \text{ m}$ is anchored specifically to the SI convention, where spatial displacement is measured in metres.

7.3 Consequence for the Planck Charge q_P

The Planck charge in EWT represents the maximum fundamental geometric amplitude of the BCC lattice:

$$q_P = \frac{e_{\text{geom}}}{\sqrt{\alpha_{\text{geom}}}}. \quad (75)$$

Evaluating this relation with $e_{\text{geom}} = 1.602176634 \times 10^{-19} \text{ m}$ yields:

$$q_P = 1.8755478 \times 10^{-18} \text{ m}. \quad (76)$$

The resulting quantity q_P is therefore an absolute spatial length of the lattice. The zero-calibration derivation of the statutory neutrino radius $r_\nu = q_P \cdot S_{\text{tot}}$ is a purely geometric relation mapping this amplitude scale to the lattice step.

8 Geometric Deficit and Density Hierarchy of the Neutrino

The neutrino soliton serves as the reference wave centre for the BCC vacuum. Its geometric radius r_ν , derived in Section 5, sets the fundamental length scale from which the EMC density hierarchy follows.

At this stage the EMC spacing λ_l is treated as a formal geometric parameter. Its numerical value is fixed later by the self-consistent gravitational identity of Section 11.6, where the Planck-length condition and the geometric expression for G form a closed algebraic system. The density hierarchy below therefore uses λ_l symbolically before that value is substituted.

This geometric saturation limit and the associated density hierarchy follow from the EWT granular density model developed by Yee [11].

1. Absolute Maximum Capacity ($N_{\nu,\max}$)

$$N_{\nu,\max} = \left(\frac{r_\nu}{\lambda_l}\right)^3 \approx 5.3004 \times 10^{54} \quad (77)$$

2. Statutory Background Density ($N_{\nu,\text{stat}}$)

$$N_{\nu,\text{stat}} = \left(\frac{r_\nu}{2\lambda_{le}}\right)^3 \approx 3.2986 \times 10^{52} \quad (78)$$

3. Effective Gravitational Density ($N_{\nu,\text{eff}}$)

The effective density inside the electron soliton is obtained from the statutory density and the geometric dilution factor X_{eff} :

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (79)$$

where X_{eff} is the geometric dilution factor defined in Section 11.6.

8.1 Unified Geometric Coupling

The transition from the statutory background to the effective density is governed by the unified coupling operator C_{unif} and the geometric dilution factor X_{eff} , already introduced in Section 6. Both quantities are fixed by the BCC lattice geometry and the electron wave-centre count $K_{WC} = 10$.

The resulting effective gravitational density is

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}} \approx 6.247 \times 10^{48}. \quad (80)$$

This value follows from the geometric dilution of the statutory vacuum by the soliton wave structure. The concept of such a density deficit and its role in gravitational emergence originates from the EWT volume-deficit models of Yee [11, 1]. In the present formulation the deficit is not fitted; it is a direct consequence of the same BCC geometry that determines α_{geom} , r_ν , and λ_l .

The extreme dilution of approximately 99.98% relative to $N_{\nu,\text{stat}}$ explains the weakness of gravity as a pressure deficit within the high-density medium.

9 Speed of Light as the Metric of Spacetime

Before deriving the gravitational constant, the role of the speed of light c must be addressed. In the conventional formulation, c is treated as a fundamental constant, empirically determined and independent of any underlying structure. Within the EWT framework, this status is revised: c is not an independent parameter but the intrinsic metric conversion factor between the spatial and temporal dimensions of the BCC lattice, determined entirely by the discrete geometry of the elastic medium.

9.1 The Causal Structure of the BCC Lattice

The BCC spacetime lattice is characterised by three distinct density levels that define its structural states:

- **Statutory density** $N_{\nu,\text{stat}}$: the equilibrium density of the undisturbed vacuum, derived in Eq. (78).
- **Effective density** $N_{\nu,\text{eff}}$: the reduced density inside a soliton (matter-occupied region), derived in Eq. (99).
- **Maximum density** $N_{\nu,\text{max}}$: the absolute saturation limit of the lattice, given by Eq. (77).

The lattice is characterised by two fundamental geometric scales:

- **The spatial step**: the inter-constituent distance λ_l , which follows from the packing geometry of the Elastic Medium Constituents (EMCs) and is identified with the Planck length. Its value is fixed by the statutory neutrino radius r_ν and the Eulerian dilution factor $2e$ through the relation

$$\lambda_l = \frac{r_\nu}{2e N_{\nu,\text{stat}}^{1/3}}, \quad (81)$$

where $N_{\nu,\text{stat}}$ is the statutory background density. Equivalently, it appears in the uncorrected neutrino wavelength

$$\lambda_{\text{uncorr}} = 2q_P e^2, \quad (82)$$

which, after the geometric correction g_v , yields the statutory radius $r_\nu = \lambda_{\text{uncorr}}/g_v$. The spatial step λ_l is thus a derived property of the BCC lattice, not an independent input.

- **The temporal step**: the fundamental cycle time t_p , which represents the characteristic oscillation period of an EMC in the lattice. In the spring-mass representation of the BCC medium, this period is determined by the effective elastic constant of the lattice and the Planck mass, both of which are themselves consequences of the lattice geometry (Sec. 31.8). The formal derivation of t_p from first principles is a natural direction for future research; for the present purposes, it suffices to note that t_p is a structural invariant of the lattice, defined by the discrete causal structure itself.

The Planck charge q_P is not an independent parameter but the fundamental amplitude scale of the BCC lattice. It is related to the elementary charge e through the fine-structure constant:

$$e^2 = \alpha q_P^2. \quad (83)$$

This relation follows directly from the definitions of α and q_P , and it holds identically in both SI units (where $q_P = \sqrt{4\pi\epsilon_0\hbar c}$) and in the EWT amplitude representation (where both charges are measured in meters). It expresses the fact that the elementary charge is the lattice amplitude reduced by the coupling factor α .

9.2 Axiom: The Maximum Propagation Speed

The following fundamental axiom is posited:

In the BCC lattice at the statutory density $N_{\nu,\text{stat}}$, there exists a maximum propagation speed c for any disturbance. This speed is a structural property of the lattice, determined by its density and elastic response, and is independent of the amplitude or frequency of the disturbance.

This axiom is physically motivated: in any elastic medium with finite density and stiffness, there exists a speed of propagation (the speed of sound in the medium). The BCC lattice, as a discrete elastic medium, is no exception. The speed c is therefore not an empirical input but a derived property of the lattice, on the same footing as the speed of sound in a solid.

In any discrete causal manifold, the maximum propagation speed is fixed by the ratio of the spatial step to the temporal step:

$$c \equiv \frac{\lambda_l}{t_p}. \quad (84)$$

Because the speed of light is the fixed metric conversion $c \equiv \lambda_l/t_p$, specifying λ_l therefore fixes the temporal step $t_p = \lambda_l/c$. In the natural units of the lattice ($c = 1$) the spatial and temporal steps are identical.

This relation is not a postulate nor an empirical input; it is the definition of the causal structure of the lattice, expressing the unique conversion factor between the temporal and spatial coordinates in the metric:

$$ds^2 = -c^2 dt^2 + dx^2 + dy^2 + dz^2. \quad (85)$$

9.3 Consequences: Density-Dependent Propagation Speed

The axiom immediately implies that the propagation speed in the lattice is a function of the local EMC density:

$$v(N_\nu) = c \cdot f\left(\frac{N_\nu}{N_{\nu,\text{stat}}}\right), \quad (86)$$

where the function f encodes the elastic response of the lattice. The three density regimes yield distinct physical consequences:

- **In vacuum** ($N = N_{\nu,\text{stat}}$), the speed is exactly c , explaining the constancy of the speed of light in free space. The vacuum is defined as the region where the lattice maintains its statutory density.
- **In matter** ($N = N_{\nu,\text{eff}} < N_{\nu,\text{stat}}$), the speed is reduced, providing a fundamental mechanism for refraction and the slowing of light in media. This is the origin of the refractive index $n = c/v > 1$.
- **In the extreme EMC packaging density limit** ($N \rightarrow N_{\nu,\text{max}}$), the lattice approaches its elastic saturation limit. The propagation properties of this regime — relevant to early-universe cosmology — lie beyond the scope of the present analysis and are reserved for future work.

The ratio of the spatial step to the temporal step in the lattice gives the maximum propagation speed in the statutory vacuum as defined in eq. 84.

Remark on the status of t_p in natural units. The preceding analysis noted that the formal derivation of the temporal step t_p from the elastic constants of the BCC medium remains an open objective in SI units. Within the natural units of the lattice ($c = 1$), however, this problem does not arise: the defining relation $c \equiv \lambda_l/t_p$ immediately yields

$$t_p = \frac{\lambda_l}{c} = \lambda_l, \quad (87)$$

so the lattice possesses a *single* fundamental scale λ_l , and t_p is not an independent quantity but an alternative labelling of the same geometric step in the temporal direction. The open objective

of deriving the *numerical value* of c in SI units (metres per second) is therefore reframed as a question about the external convention that separates the metre from the second — not a question about the internal structure of the lattice. Within EWT, the lattice is characterised by one geometric primitive: λ_l .

Remark on the Dimensional Status of c :

The speed of light c does not appear in any of the dimensionless predictions of the EWT framework (the fine-structure constant α , the anomalous magnetic moments a_e , a_μ , a_τ , or the lepton mass ratios). It enters only when expressing dimensional SI quantities such as G or m_e , where it plays the role of a *metric conversion factor* between the spatial step λ_l and the temporal step t_p of the BCC lattice ($c \equiv \lambda_l/t_p$). In natural units ($c = 1$), the EWT framework is parameter-free: all physical predictions reduce to dimensionless ratios determined by BCC lattice topology alone. The appearance of c in SI expressions reflects the unit system's convention for separating spatial and temporal dimensions, not an independent physical input to the theory. Its numerical value in SI units is therefore a consequence of the arbitrary definitions of the metre and the second, not a fundamental property of the vacuum lattice. This status is consistent with the SI 2019 definition, in which c is an exact definitional constant rather than a measured quantity.

With this geometric interpretation of the speed of light, the base gravitational scaling may now be derived.

10 The Physical Origin of Relativity: Wave-Mechanical Lorentz Contraction

As established in Sec. 9, the speed of light c is the structural conversion factor between the spatial and temporal steps of the BCC lattice. The present section demonstrates that this same value is measured by all inertial observers, not as a primary postulate, but as a mechanical consequence of the wave-structure of matter. The derivation follows the Doppler-based approach developed by Gabriel LaFrenière [51] and historically proposed by H.A. Lorentz [52] and G.F. FitzGerald [53] as a physical explanation of the Michelson–Morley null result.

10.1 Doppler-Induced Compression of the Standing-Wave Soliton

In EWT, a particle is a standing wave (soliton) formed by the interference of incoming and outgoing waves in the BCC medium. When such a soliton moves relative to the lattice with velocity $v = \beta c$, the underlying waves undergo an anisotropic Doppler shift.

Let λ_0 be the wavelength of the soliton at rest. For a soliton moving at speed v , the forward-propagating wave is compressed to λ_f and the backward wave is expanded to λ_b :

$$\lambda_f = \lambda_0(1 - \beta), \quad \lambda_b = \lambda_0(1 + \beta). \quad (88)$$

The resulting standing-wave wavelength in the direction of motion, λ' , is the geometric mean of the two, modulated by the requirement of phase synchronization across the soliton's diameter:

$$\lambda' = \sqrt{\lambda_f \cdot \lambda_b} = \lambda_0 \sqrt{1 - \beta^2} = \frac{\lambda_0}{\gamma}, \quad (89)$$

1043 where $\gamma = (1 - \beta^2)^{-1/2}$ is the Lorentz factor. This result shows that the physical distance
 1044 between the wave-center nodes — the “size” of the particle — must contract.

1045 10.2 The Michelson–Morley Null Result as a Mechanical Necessity

1046 The invariance of the measured speed of light in the Michelson–Morley experiment is usually
 1047 interpreted as a property of spacetime. In EWT, it is a property of the **measuring apparatus**.
 1048 Because all matter (including the interferometer arms) consists of waves in the BCC lattice, the
 1049 apparatus itself undergoes a physical contraction:

- 1050 1. **Longitudinal arm ($L_{\parallel}$):** Contracts by exactly $1/\gamma$ owing to the wave-node compression
 1051 derived above.
- 1052 2. **Transverse arm ($L_{\perp}$):** Remains unchanged in length, but the wave path is elongated by
 1053 γ because of the diagonal trajectory through the medium.

1054 The total round-trip times for the longitudinal path ($t_{\parallel}$) and transverse path ($t_{\perp}$) become
 1055 identical:

$$t_{\parallel} = \frac{L_0/\gamma}{c-v} + \frac{L_0/\gamma}{c+v} = \frac{2L_0}{c} \gamma, \quad t_{\perp} = \frac{2L_0 \sqrt{1 + (v\gamma/c)^2}}{c} = \frac{2L_0}{c} \gamma. \quad (90)$$

1056 Thus $t_{\parallel} = t_{\perp}$. The null result is not due to the absence of a medium, but because the
 1057 wave-mechanical contraction of the soliton perfectly masks the motion through the lattice.

1058 **Remark on time dilation:** Substituting $c = 1$ (the natural units of the BCC lattice,
 1059 Sec. 9) into the Michelson–Morley round-trip times yields $t_{\parallel} = t_{\perp} = 2L_0\gamma$ for both arms. In
 1060 the lattice rest frame the round-trip time is therefore $t = 2L_0\gamma$. A clock carried by the moving
 1061 interferometer, whose rate is dilated by $1/\gamma$, measures

$$t' = \frac{t}{\gamma} = 2L_0,$$

1062 the same elapsed time as an identical apparatus at rest in the BCC lattice. The oscillation period
 1063 of the soliton therefore dilates to $T' = \gamma T_0$, with the observed tick rate scaling as $f' = f_0/\gamma$ —
 1064 the temporal counterpart of the spatial contraction derived above.

1065 11 The Geometric Identity of G : Derivation and Consistency

1067 The core hypothesis of the Energy Wave Theory (EWT) is that the gravitational constant $\mathbf{G}$ is
 1068 not a fundamental constant but an **emergent, calculated geometric identity** derived from
 1069 the electron’s geometric parameters and the BCC lattice topology. This section derives a precise
 1070 $\hbar$ -independent formula for $\mathbf{G}$ and explains the physical meaning of its scaling terms.

1071 11.1 Derivation of G from Electron Scaling (The $\hbar$ -Independent Base)

1072 Traditional definitions of $\mathbf{G}$ rely on Planck units, which inherently contain the reduced Planck
 1073 constant ($\hbar$). EWT posits that the gravitational constant is derived from the scaling of the
 1074 electron’s properties ($\mathbf{m}_e, \mathbf{r}_e$), which are geometric wave-based quantities.

1075 The Base Gravitational Scaling ($\mathbf{G}_{\text{Base}}$)

1076 The fundamental scaling constant for gravity is established by the ratio of energy density to
 1077 mass, using the speed of light (c), the classical electron radius ($\mathbf{r}_e$), and the electron mass ($\mathbf{m}_e$):

$$\mathbf{G}_{\text{Base}} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \approx 2.780252 \times 10^{32} \text{ m}^3 \text{kg}^{-1} \text{s}^{-2} \quad (91)$$

1078 This term is the sole source of the required physical units for the gravitational constant:

$$\left[\frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \right] = \frac{(\text{m} \cdot \text{s}^{-1})^2 \cdot \text{m}}{\text{kg}} = \text{m}^3 \cdot \text{kg}^{-1} \cdot \text{s}^{-2} \quad (92)$$

1079 All subsequent geometric factors in the final identity for $\mathbf{G}$ are therefore dimensionless.

1080 The $\hbar$ -Independence of $\mathbf{G}_{\text{Base}}$

1081 The form of $\mathbf{G}_{\text{Base}}$ is inherently independent of $\hbar$. This is demonstrated by substituting the
 1082 standard definition of the classical electron radius ($\mathbf{r}_e = \alpha \frac{\hbar}{\mathbf{m}_e c}$) into the conventional expression
 1083 for the gravitational constant based on particle properties ($\mathbf{G}_{\text{Base}} = \alpha \frac{\hbar c}{\mathbf{m}_e^2}$):

$$\mathbf{G}_{\text{Base}} = \alpha \frac{\hbar c}{\mathbf{m}_e^2} = \alpha \frac{\left(\frac{\mathbf{r}_e \mathbf{m}_e c}{\alpha} \right) c}{\mathbf{m}_e^2} = \frac{\mathbf{r}_e \mathbf{m}_e c^2}{\mathbf{m}_e^2} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e} \quad (93)$$

1084 The cancellation of $\hbar$ confirms that the base gravitational scale is a classical geometric prop-
 1085 erty of the electron soliton ($\mathbf{m}_e, \mathbf{r}_e, c$), rather than a purely quantum effect.

1086 Status of m_e and r_e in the Present Work

1087 In the current formulation, m_e , r_e , and c are the metric and structural inputs used to anchor the
 1088 electron soliton. The radius r_e is related to the geometric neutrino anchor by

$$r_e = 100 r_\nu, \quad (94)$$

1089 while m_e is constrained by the $E \propto r^5$ scaling law discussed in Section 15.1. Their full derivation
 1090 from the BCC lattice alone is a central open objective.

1091 The subsequent derivation of G therefore contains no free dimensional parameters: the only
 1092 inputs are r_e , m_e , c , and the elementary charge amplitude e . In natural units ($c = 1$), the
 1093 number of independent inputs reduces further, and the gravitational constant becomes a purely
 1094 geometric prediction.

1095 The Final Geometric Identity for G

1096 The observed gravitational constant $\mathbf{G}$ is obtained by scaling $\mathbf{G}_{\text{Base}}$ with the total dimensionless
 1097 geometric weakness factor. In the zero-calibration formulation, this factor is built solely from
 1098 the geometric soliton core A_π , the effective BCC stiffness N_{geom} , the electron wave-centre count
 1099 $K_{WC} = 10$, and the effective volume deficit $N_{\nu, \text{eff}}$.

1100 The geometric identity for $\mathbf{G}$ is therefore:

$$\mathbf{G} \equiv \mathbf{G}_{\text{Base}} \cdot \frac{1}{A_\pi} \cdot \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}} \quad (95)$$

1101 The only dimensional factor in this expression is $\mathbf{G}_{\text{Base}}$. Every other factor is a pure geometric
 1102 number determined by the BCC lattice and the electron soliton.

1103 Geometric Dependence on λ_l

1104 The effective volume deficit $N_{\nu,\text{eff}}$ depends on the EMC spacing λ_l through the statutory density:

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad N_{\nu,\text{stat}} = \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (96)$$

1105 Thus Eq. (95) defines G as a function of the formal parameter λ_l . This is not a fault of the
 1106 model; it is the expected self-consistent coupling between gravity and the fundamental lattice
 1107 spacing. The value of λ_l will be fixed in Section 11.6 by combining the geometric G with the
 1108 Planck-length definition.

1109 Compact ϵ_M Form

1110 Using the geometric magnetic deficit

$$\epsilon_M = \frac{1}{N_{\text{geom}}\pi^3}, \quad (97)$$

1111 Eq. (95) can also be written as

$$\mathbf{G} = \frac{\mathbf{G}_{\text{Base}}}{A_\pi} \left(\frac{\epsilon_M \pi^3}{A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu,\text{eff}}}}. \quad (98)$$

1112 This form shows that gravity and the magnetic deficit share the same geometric origin. It also
 1113 makes clear that the weakness of gravity is a consequence of the cubic suppression by ϵ_M/A_π ,
 1114 followed by the surface projection $N_{\nu,\text{eff}}^{-1/2}$.

1115 11.2 The Gravitational Identity Flow: From Electromagnetic Base to 1116 Surface Transition

1117 The derivation of the Gravitational Constant $\mathbf{G}$ follows a systematic, multi-step geometric flow.
 1118 This process resolves the scale disparity between electromagnetic and gravitational interactions
 1119 by accounting for the displacement of the medium's constituents within the Soliton structure.

1120 **Step 1: Establishment of the EM Base ($\mathbf{G}_{\text{Base}}$):** The process is initiated by defining $\mathbf{G}_{\text{Base}}$,
 1121 which links the classical electron radius (r_e) and its mass (m_e). This term represents the
 1122 maximum potential coupling scale before geometric dilution is applied.

1123 **Step 2: Geometric Stability Factor (A_π^{-1}):** The first scaling step introduces the normalization
 1124 to the static wavelength-to-radius ratio of the Soliton.

1125 **Step 3: Nodal Push-Out Potential (Ω_{Push}):** This phase incorporates the volumetric redistri-
 1126 bution of energy. By applying the cubic factor $(N_{\text{geom}}A_\pi)^{-3}$, the model quantifies the
 1127 structural dilution of the soliton in the BCC lattice.

1128 **Step 4: Geometric Surface Transition ($\mathbf{T}_{\text{Surface}}$):** The conversion of the internal displacement
 1129 into the observable gravitational force is governed by the factor $(K_{WC} \cdot \sqrt{N_{\nu,\text{eff}}})^{-1}$. Here,
 1130 $K_{WC} = 10$ Wave Centers act as the primary operators of the Push-Out mechanism, evacu-
 1131 ating the medium from its statutory density to the effective density of the matter-occupied
 1132 region.

1133 The square root ($N_{\nu,\text{eff}}^{-1/2}$) serves as the surface transition operator, projecting the three-
 1134 dimensional internal packing deficit onto the two-dimensional effective surface of the Soli-
 1135 ton. Gravity is thus revealed as an emergent, pressure-driven phenomenon acting on this
 1136 surface.

1137 **Step 5: Final Gravitational Identity:** The integration of these modular scales yields the geo-
 1138 metric identity for $\mathbf{G}$ given in Eq. (95).

1139 Physical Significance

1140 The extreme weakness of gravity is a direct consequence of this hierarchical dilution. While the
 1141 Soliton's mass is defined by high-frequency energy localization, the gravitational constant $\mathbf{G}$ is
 1142 a measure of the effective displacement deficit. The transition from the statutory vacuum to the
 1143 diluted interior creates a pressure gradient, whereby the universal medium strives for equilibrium
 1144 by filling the geometric void.

1145 The Holographic Nature and Experimental Implications

1146 The presence of the square root ($\sqrt{N_{\nu,\text{eff}}}$) in the final identity reinforces the principle that
 1147 gravity is an emergent surface phenomenon. By projecting the three-dimensional volumetric
 1148 deficit onto a two-dimensional boundary, the model aligns with holographic and thermodynamic
 1149 interpretations of gravitational flux.

1150 11.3 Formalization of Soliton Geometric Density $\rho(r)$

1151 To avoid ambiguity between energy density ρ_E and the packing density, the internal density
 1152 function $\rho(r)$ is introduced to represent the local distribution of Elastic Medium Constituents
 1153 (EMC) within the Soliton. This profile is physically important, but the numerical value of the
 1154 effective deficit is fixed algebraically by the unified coupling described in Section 8:

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (99)$$

1155 where X_{eff} is the geometric dilution factor from Section 11.6 and Eq. (109). The radial profile
 1156 $\rho(r)$ is compatible with this value, and the structural parameters of any assumed profile do not
 1157 enter as free inputs into the gravitational identity.

1158 11.4 Numerical Verification and the Unitary Mapping Operator $\mathcal{U}$

1159 Numerical Consistency

1160 Using the geometric value N_{geom} and the self-consistent λ_l from Eq. (114), the geometric identity
 1161 Eq. (95) gives

$$G_{\text{EWT}} \approx 6.67752 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}. \quad (100)$$

1162 The corresponding CODATA 2022 value is

$$G_{\text{CODATA}} = 6.674305 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}, \quad (101)$$

1163 so the relative deviation is approximately 0.048%.

1164 This is a genuine geometric prediction.

1165 The Unitary Mapping Operator $\mathcal{U}_{\text{Geom} \rightarrow G}$

1166 The final step in the geometric formalization is the introduction of the **Unitary Mapping Op-**
 1167 **erator** $\mathcal{U}$, which symbolically represents the non-linear transformation of the Soliton's internal
 1168 geometry into the macroscopic gravitational constant:

$$\mathcal{U}_{\text{Geom} \rightarrow G} : A_\pi, N_{\text{geom}}, N_{\nu, \text{eff}} \mapsto G \equiv \frac{c^2 r_e}{m_e} \cdot \Omega_G. \quad (102)$$

1169 This operator formalizes that G is not a standalone fundamental constant but a direct manifes-
 1170 tation of the geometric scaling applied to the electron's $\hbar$ -independent base.

1171 11.5 Formal Definition of the Operator $\mathcal{U}$: Mapping Geometric Pa- 1172 rameters to G

1173 To codify the micro-macro transformation in a rigorous mathematical manner, a nonlinear func-
 1174 tional operator $\mathcal{U}$ is defined:

$$\mathcal{U} : \mathcal{D} \subset \mathbb{R}^n \rightarrow \mathbb{R}, \quad \mathcal{U}(\mathbf{P}) \mapsto G \quad (103)$$

1175 where the parameter vector $\mathbf{P}$ contains all relevant microscopic variables of the model. This
 1176 functional approach expresses the gravitational constant G as a product of the **Base Soliton**
 1177 **Identity** ($\mathbf{G}_{\text{Base}}$) and a **Geometric Scaling Functional** (F_{geom}):

$$\mathcal{U}(\mathbf{P}) = \mathbf{G}_{\text{Base}} \cdot F_{\text{geom}}(\mathbf{P}), \quad \mathbf{G}_{\text{Base}} = \frac{c^2 \mathbf{r}_e}{\mathbf{m}_e}. \quad (104)$$

1178 The explicit geometric form used in this work is

$$\mathcal{U}(\mathbf{P}) = \frac{c^2 r_e}{m_e} \cdot \frac{1}{A_\pi} \cdot \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}} \quad (105)$$

1179 where A_π is the core geometric factor and $N_{\nu, \text{eff}}$ is the effective volume deficit derived from the
 1180 unified coupling C_{unif} .

1181 Properties of the Operator $\mathcal{U}$

- 1182 • **Non-linearity:** The mapping is characterized by cubic scaling of the stiffness factor and
 1183 an inverse square-root dependency on the effective constituent count.
- 1184 • **Monotonicity:** For a fixed statutory background, any increase in $N_{\nu, \text{eff}}$ results in a de-
 1185 terministic decrease in the emergent value of G .
- 1186 • **Zero calibration:** The operator contains only geometric and structural inputs: $A_\pi, N_{\text{geom}},$
 1187 $K_{WC}, N_{\nu, \text{eff}}$.

1188 the G implementation result showed in table 4.

Table 4: Numerical Verification of the Gravitational Constant G within the Geometric EWT Framework

Parameter / Result	Numerical Value	Source and Physical Context
I. Base Soliton Identity	$2.7802522591 \times 10^{32}$	$G_{\text{Base}} = \frac{c^2 r_e}{m_e}$. Fundamental Soliton base.
II. Raw Geometry Value	$6.6804369615 \times 10^{-11}$	$G_{\text{EWT, raw}}$. Pure $K + 1$ projection; error 0.09187% relative to CODATA.
III. Geometric Result	$6.6775199755 \times 10^{-11}$	Zero-calibration geometric G . Uses L_p^{geom} and N_{geom} ; error 0.04817%.
IV. CODATA Target	$6.6743050000 \times 10^{-11}$	Experimental reference value (CODATA 2022).

Note: All values are expressed in units of $m^3 kg^{-1} s^{-2}$.

11.6 Geometric Emergence of the Planck Length

The Planck length in EWT is identified with the fundamental EMC spacing λ_l . In the zero-calibration formulation, λ_l is not taken from experiment; it follows from the geometric identity for the gravitational constant and the Planck-length definition.

Before the effective dilution factor X_{eff} can be written down, the unified coupling operator C_{unif} that governs it must be derived. The operator bridges the raw geometric projection of the wave centres onto the BCC lattice with the electromagnetic response of the medium, and its three terms each have a distinct structural origin.

The Fundamental Geometric Ratio: C_{Raw}

Prior to any electromagnetic coupling, the model identifies the pure interaction ratio between the soliton's wave centres and the background lattice. This factor,

$$C_{\text{Raw}} = 1 + \frac{1}{K_{WC}}, \quad (106)$$

is the “ideal” geometric scaffold of the displacement. The term $1/K_{WC}$ is the harmonic reciprocal of the $K_{WC} = 10$ wave centres; it normalises the global volume deficit to the individual node's displacement capacity. The additive $+1$ is the statutory equilibrium of the medium, the unperturbed vacuum state that the correction is applied on top of. For $K_{WC} = 10$ this gives $C_{\text{Raw}} = 1.1$, the baseline efficiency of the vacuum displacement before any elastic or fine-structure corrections.

The Lattice Projection Factor L_p^{geom}

The natural geometric starting point for the interfacial correction is the ideal BCC projection factor

$$L_p^{\text{geom}} = \frac{2}{\sqrt{3}} \approx 1.154700538, \quad (107)$$

which arises as the inverse of the dimensionless nearest-neighbour distance ($d_{NN}/a = \sqrt{3}/2$) in the $Im\bar{3}m$ lattice. Its combination $\pi L_p^{\text{geom}} = 2\pi/\sqrt{3}$ is the dimensionless fundamental wavevector

for a standing wave along the [111] body diagonal, capturing the projection of the 3D lattice onto the 2D soliton interface.

The Unified Bridge: C_{unif}

The full operator adds the electromagnetic coupling across the lattice interface:

$$C_{\text{unif}} = \frac{1}{K_{WC}} + 1 + \frac{\alpha_{\text{geom}}}{\pi L_p^{\text{geom}}}. \quad (108)$$

The three terms correspond to the three distinct contributions of the medium's response:

- **Harmonic reciprocal** $1/K_{WC}$: the specific contribution of the $K_{WC} = 10$ wave centres, ensuring that the global deficit is normalised to the individual node's displacement capacity.
- **Unitary baseline** $+1$: the statutory equilibrium of the medium, the unperturbed vacuum state. It ensures the correction is additive to the existing background density $N_{\nu,\text{stat}}$, maintaining continuity of the elastic field.
- **Interfacial tension bridge** $\alpha_{\text{geom}}/(\pi L_p^{\text{geom}})$: the electromagnetic strain coupled through the lattice projection factor and the geometric π . This term scales the large-scale volumetric deficit down to the interfacial tension at the soliton boundary.

With C_{unif} established, the effective dilution factor follows directly:

$$X_{\text{eff}} = \frac{A_\pi 3 K_{WC} \sqrt{2}}{C_{\text{unif}}}, \quad (109)$$

where $A_\pi = 4\pi^3 + \pi^2 + \pi$ is the geometric core of the soliton. The numerator counts the active geometric budget of the soliton (the core geometry A_π , the three spatial dimensions, the K_{WC} wave centres, and the $\sqrt{2}$ face-diagonal coupling); the denominator C_{unif} is the structural impedance of the medium through which that budget is projected. The ratio is the geometric dilution of the statutory background density inside the soliton.

The self-consistent derivation of λ_l starts from the Planck-length definition,

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}, \quad (110)$$

in which $\hbar_{\text{geom}}$ is given by Eq. (70), while G_{geom} is the geometric gravitational constant whose explicit form is derived in Section 11. In the present section it is sufficient to use its geometric structure,

$$G_{\text{geom}} = \frac{G_{\text{Base}}}{A_\pi} \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu,\text{eff}}}}, \quad (111)$$

where

$$G_{\text{Base}} = \frac{c^2 r_e}{m_e}. \quad (112)$$

The effective density $N_{\nu,\text{eff}}$ is related to the statutory density $N_{\nu,\text{stat}}$ by

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad N_{\nu,\text{stat}} = \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (113)$$

Substituting these expressions into the Planck-length definition cancels m_e , c , and the common A_π factors. Solving the resulting algebraic equation for λ_l gives

$$\lambda_l = \left[\frac{r_e^2 \sqrt{X_{\text{eff}}}}{\alpha_{\text{geom}} A_\pi^4 N_{\text{geom}}^3 K_{WC} \left(\frac{r_\nu}{2e}\right)^{3/2}} \right]^2, \quad (114)$$

where e is Euler's number. Normalized form is:

$$\lambda_l = \left[\frac{r_e^2 \sqrt{\frac{3\sqrt{2} A_\pi}{C_{\text{unif}}}}}{\alpha_{\text{geom}} A_\pi^4 N_{\text{geom}}^3 \sqrt{K_{WC}} \left(\frac{r_\nu}{2e}\right)^{3/2}} \right]^2. \quad (115)$$

Equation (115) substitutes the definition of X_{eff} directly, so that the wave-centre count enters once through $\sqrt{K_{WC}}$ rather than twice. The fine-structure constant appears twice in the expression, but in two distinct roles: the leading α_{geom} is the electromagnetic coupling of the soliton itself, while the α_{geom} inside C_{unif} is the electromagnetic strain across the soliton–vacuum interface. The two appearances are not a redundancy; they reflect the two surfaces through which the same coupling is projected.

Planck introduced this length as a formal dimensional combination of $\hbar$, G , and c , without reference to a microscopic substrate. In the present framework, the same quantity appears as the self-consistent solution of the geometric BCC equations, thereby providing a physical origin for the scale that Planck treated only as a formal unit.

Equations (114) and (115) are therefore not an independent ansatz. They are the direct consequence of combining the geometric fine-structure constant, the geometric gravitational scaling, and the Planck-length definition into a single closed algebraic constraint. Here e is Euler's number and r_ν is the geometric neutrino radius derived in Section 5.

Numerically,

$$\lambda_l \approx 1.6166464 \times 10^{-35} \text{ m}. \quad (116)$$

The CODATA value is

$$\lambda_{l,\text{CODATA}} = 1.6162 \times 10^{-35} \text{ m}, \quad (117)$$

so the relative deviation is approximately 0.0276%. This is a genuine geometric prediction.

X_{eff} is not a free parameter; it is the geometric bridge that connects the statutory EMC background to the effective soliton deficit. It encapsulates how $K_{WC} = 10$, the ideal BCC projection, and the geometric core A_π jointly dilute the vacuum density inside matter.

11.7 Consistency with the Planck Charge

The geometric Planck charge was derived earlier as

$$q_P = \frac{e}{\sqrt{\alpha_{\text{geom}}}}. \quad (118)$$

With the above values,

$$q_P \approx 1.8755478 \times 10^{-18} \text{ m}, \quad (119)$$

which matches the expected amplitude scale.

The fact that λ_l , q_P , and $\hbar_{\text{geom}}$ all emerge from the same BCC geometry confirms that the model does not treat the Planck scale as an external boundary but as an internal consequence of the lattice structure.

1266 11.8 Electromagnetic Consistency Check

1267 In SI units, the relation between charge, $\hbar$, and α is

$$e^2 = 4\pi\epsilon_0\hbar c\alpha. \quad (120)$$

1268 Substituting the geometric expression for $\hbar$, Eq. (70), cancels α_{geom} identically and yields

$$e^2 = 4\pi\epsilon_0 m_e c^2 r_e. \quad (121)$$

1269 In the natural units of the BCC lattice ($c = 1$, $4\pi\epsilon_0 = 1$; see Section 9), this reduces to the
1270 purely geometric identity

$$e^2 = m_e r_e. \quad (122)$$

1271 This is not an independent derivation of e , since m_e and r_e are inputs, but it is a powerful internal
1272 consistency test: it shows that the electromagnetic scale (e) is rigidly tied to the soliton's mass
1273 and radius, with no residual dependence on $\hbar$ or α .

1274 11.9 Status of Inputs

1275 The only experimental inputs in model are

$$r_e, \quad m_e, \quad c, \quad e. \quad (123)$$

1276 In natural units ($c = 1$; see Section 9), c is a unit conversion and m_e is geometrically tied to r_e
1277 through the r^5 scaling law. In SI units the relation between charge, $\hbar$, and α is $e^2 = 4\pi\epsilon_0\hbar c\alpha$. In
1278 the EWT framework ϵ_0 is not an independent input: together with μ_0 it is fixed by the metric
1279 condition $c^2 = 1/(\mu_0\epsilon_0)$ and therefore carries no new geometric information. No calibrated
1280 parameters appear in this section.

1281 The quantities G_{geom} , λ_l , $\hbar_{\text{geom}}$, and α_{geom} are not independent predictions. They form a
1282 single closed algebraic system fixed by the BCC lattice geometry, the electron soliton inputs
1283 r_e, m_e, c, e , and the geometric self-consistency condition

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}. \quad (124)$$

1284 Solving this system is the geometric self-consistency of the model, not a stepwise derivation of
1285 one constant from another.

1286 In the standard framework the Planck-length relation links three independent empirical con-
1287 stants. In the present model the same relation emerges as an internal geometric condition,
1288 because both $\hbar_{\text{geom}}$ and G_{geom} are already determined by the BCC lattice. The Planck scale
1289 is therefore not imported from the Standard Model; it is reconstructed as a consequence of the
1290 underlying geometry.

1291 11.10 Duality of Soliton Density

1292 Presented model inherently describes a fundamental duality of densities within the Soliton. The
1293 localized energy density ρ_E inside the Soliton must be higher than the surrounding medium, due
1294 to localized standing wave energy, to account for its mass $E = mc^2$. Conversely, the geometric
1295 packing density function $\rho(r)$ must be lower than the uniform density of the surrounding space,
1296 creating the measurable packing deficit $N_{\nu, \text{eff}}$.

1297 This dichotomy means the Soliton is a region of high energy but low geometric packing
1298 efficiency. The dynamic processes described in models unifying mass and charge as wave energy

[26, 29, 15] can be hypothesized to be the cause of the packing density deficit of the EMC, by continuously forcing the Soliton's wave components outward, defining the effective volume and maintaining its stability.

The accompanying constant geometric term A_π^{-1} is specifically interpreted here as the Geometric Stability Factor. This factor quantifies the fixed boundary ratio resulting from the continuous dynamic process of outward forcing on the Soliton's internal wave structure.

This definition of density introduces a central principle of the Enhanced EWT Model: gravity is an emergent, pressure-driven phenomenon that acts on the Soliton's effective surface, as the universal medium strives for equilibrium by filling this geometric deficit. This provides a basis for interpreting gravity as a push force induced by a vacuum pressure gradient [34].

11.11 The Degraded EMC Wall: Spherical Masking and Isotropy

A fundamental puzzle in any geometric theory of matter is how an asymmetric, rotating not perfect spherical soliton can generate a perfectly isotropic gravitational field. The resolution lies in a structural boundary layer that surrounds every soliton – the **Degraded EMC Wall**.

The Degraded EMC Wall is a spherical shell of finite thickness located at a radius r_{mask} where the packing density of Elastic Medium Constituents (EMCs) transitions from the diluted interior of the soliton toward the statutory background density $N_{\nu,\text{stat}}$. The wall is a region of **elevated EMC density** caused by the active push-out mechanism: as the soliton's standing waves displace EMCs from the interior, these constituents accumulate just outside the soliton boundary, creating a local density peak:

$$\rho_{\text{EMC}}(r_{\text{mask}}^-) < \rho_{\text{EMC}}(r_{\text{wall}}), \quad (125)$$

where r_{wall} denotes a point located strictly inside the Degraded EMC Wall.

The exact value of this peak relative to $N_{\nu,\text{stat}}$ depends on the balance between the internal push-out force and the external statutory pressure of the surrounding BCC lattice. In ordinary solitons this equilibrium yields a moderate peak, while in extreme gravitational environments the peak can become very large.

The Degraded EMC Wall acts as a mandatory transducer between the asymmetric core and the exterior. Because the individual EMCs are spherical units, the BCC lattice can only achieve a stable, static interface with the statutory background by adopting a spherical shape. The wall therefore enforces a spherical boundary condition on the energy density distribution emerging from the asymmetric core. The effect can be quantified by the Isotropy Operator $\mathcal{I}$ (introduced in Section 24.7).

11.11.1 Open question: Wall density relative to statutory background

The precise value of the peak EMC density within the Degraded EMC Wall, ρ_{wall} , relative to the statutory background $N_{\nu,\text{stat}}$, remains undetermined. Two scenarios are physically permissible:

- **Scenario A (asymptotic approach):** $\rho_{\text{wall}} < N_{\nu,\text{stat}}$, with the density increasing monotonically from the soliton interior toward the statutory value.
- **Scenario B (local maximum):** $\rho_{\text{wall}} > N_{\nu,\text{stat}}$, corresponding to a genuine local density peak caused by the active push-out.

Both scenarios are compatible with the integral determination of $N_{\nu,\text{eff}}$ and with the derivation of G . Future high-resolution simulations may discriminate between them. For the purpose of the present work, we treat the wall density ratio as an open parameter $\eta = \rho_{\text{wall}}/N_{\nu,\text{stat}}$.

12 Local Metric Phenomena from EMC Lattice Deformation

12.1 The Two Faces of EMC Displacement: Speed and Trajectory

In the Enhanced EWT framework, light propagation involves two distinct, though coupled, consequences of the EMC lattice strain field. They are frequently conflated in continuous medium optics, so it is necessary to state them with structural precision.

1. **Coordinate phase velocity via lattice strain.** In natural lattice units ($c \equiv 1$), the statutory speed of light is defined by the undisturbed cell ratio $c = \lambda_l/t_p = 1$. Around a matter soliton, the radial displacement of EMC nodes creates a spatial strain $\epsilon(r) = \nabla \cdot \vec{u}(r)$. This strain stretches the effective coordinate cell spacing $\lambda_l(r)$, so that a wave packet requires more fundamental time ticks t_p to traverse a unit coordinate distance. This produces an effective slowdown in coordinate speed $v(r) < 1$, encoded by an isotropic scalar refractive index $n_\gamma(r) = 1/v(r) > 1$.
2. **Trajectory deflection via restoring displacement.** The actual bending of a wave packet trajectory is driven by the vector displacement field $\vec{u}(r)$, rather than by a scalar density deficit alone. In response to the core deficit of a matter soliton, the surrounding EMC lattice develops a directed restoring displacement field:

$$\vec{u}(r) = -u_r(r) \hat{r}, \quad (126)$$

where the dimensionless radial magnitude $u_r(r)$ is the cumulative structural response to the normalized density gradient:

$$u_r(r) = \int_r^\infty \left| \nabla \left(\frac{N_\nu(r')}{N_{\text{stat}}} \right) \right| dr'. \quad (127)$$

The negative sign in Eq. (126) signifies structural displacement *toward* the central deficit. Light rays propagating through this strained lattice continuously realign along the principal axes of the displacement field, deflecting the wavefront toward the mass center.

12.2 Bridging the Vector Displacement to the Scalar Refractive Index

To connect the vector kinematics of Eq. (126) to standard ray-tracing integrals, we evaluate the scalar refractive index $n_\gamma(r)$ as the local isotropic dilatation factor induced by the dimensionless radial displacement field $u_r(r)$.

A 3D standing-wave soliton exhibits an asymptotic radial energy density deficit decaying as $1/r$. In the simplest spherical weak-field model, the normalized local EMC density takes the form

$$\frac{N_\nu(r)}{N_{\text{stat}}} = 1 - \frac{r_s}{r}, \quad (128)$$

where $r_s = 2GM$ is the gravitational radius in natural units ($c = 1$). The exact normalized gradient is therefore

$$\left| \nabla \left(\frac{N_\nu(r)}{N_{\text{stat}}} \right) \right| = \frac{r_s}{r^2}. \quad (129)$$

Substituting this gradient into Eq. (127) yields exactly

$$u_r(r) = \int_r^\infty \frac{r_s}{r'^2} dr' = \frac{r_s}{r}. \quad (130)$$

1372 The scalar refractive index $n_\gamma(r)$ represents the local isotropic dilatation factor induced by
 1373 this displacement field:

$$n_\gamma(r) = 1 + u_r(r) = 1 + \frac{r_s}{r} = 1 + 2\Phi_N(r), \quad (131)$$

1374 where $\Phi_N(r) = GM/r = r_s/(2r)$ is the dimensionless Newtonian gravitational potential per unit
 1375 energy.

1376 12.3 Asymptotic Continuous Limit and Schwarzschild Equivalence

1377 Eq. (131) corresponds to the first-order weak-field expansion of the full continuous expression:

$$n_\gamma(r) = \left(1 - \frac{2r_s}{r}\right)^{-1/2}. \quad (132)$$

1378 It is important to clarify the theoretical status of Eq. (132): in Enhanced EWT, this function
 1379 does not represent an external metric tensor imported from General Relativity, nor is it an ad
 1380 hoc optical ansatz. Rather, Eq. (132) is the *asymptotic continuous limit* of the discrete BCC
 1381 lattice deformation field around a spherical soliton core.

1382 Formally, $n_\gamma(r)$ matches the effective optical metric factor of the Schwarzschild geometry.
 1383 In EWT, however, this exact mathematical form arises physically from the nonlinear elastic
 1384 response of the EMC medium under the $1/r$ gravitational potential load, without requiring a
 1385 curved spacetime manifold.

1386 Expanding Eq. (132) binomially:

$$n_\gamma(r) = \left(1 - \frac{2r_s}{r}\right)^{-1/2} \approx 1 + \frac{r_s}{r} + \mathcal{O}\left(\left(\frac{r_s}{r}\right)^2\right), \quad (133)$$

1387 recovers the exact factor of 2 in front of $\Phi_N(r)$, providing the structural lattice foundation for
 1388 the observed $1.75''$ solar limb deflection. In the undisturbed statutory vacuum ($r_s/r \rightarrow 0$),
 1389 $n_\gamma(r) \rightarrow 1$, restoring the fundamental lattice ratio $c = \lambda_l/t_p = 1$.

1390 12.4 Mechanical Origin of Gravitational Redshift in the EMC Lattice

1391 In Enhanced EWT, both electromagnetic propagation and gravitational time dilation arise from
 1392 a single microscopic mechanism: the spatial deformation of the EMC node separation $\lambda_l(r)$
 1393 around a matter soliton.

1394 In the natural units of the BCC lattice, the speed of light is the fundamental metric conversion
 1395 factor

$$c \equiv \frac{\lambda_l}{t_p} = 1.$$

1396 Consequently, length and time share the same dimension, $[m] = [s]$, and the gravitational poten-
 1397 tial is dimensionless without the explicit c^2 factor that appears only in the SI-unit convention.
 1398 In these natural units, the Newtonian potential is simply

$$\Phi_N(r) = \frac{GM}{r}, \quad (134)$$

1399 and the gravitational radius of the source is

$$r_s = 2GM. \quad (135)$$

1400 Define the dimensionless local EMC lattice density ratio as:

$$\eta(r) \equiv \frac{N_\nu(r)}{N_{\text{stat}}} = 1 - \frac{r_s}{r} = 1 - 2\Phi_N(r), \quad (136)$$

1401 where $\Phi_N(r) = GM/r = r_s/(2r)$ in natural units.

1402 A physical clock is modeled as a standing-wave soliton whose fundamental period $T(r)$ is
 1403 determined by the internal round-trip time of a longitudinal EMC lattice wave traversing the
 1404 soliton core. Because the internal wave relies on node-to-node propagation across the same
 1405 strained lattice spacing $\lambda_l(r)$ that dictates external optics, its effective propagation rate scales
 1406 with the square root of the local node availability $\eta(r)$:

$$v_{\text{clock}}(r) = \sqrt{\eta(r)} = \sqrt{1 - 2\Phi_N(r)} \approx 1 - \Phi_N(r). \quad (137)$$

1407 For a rest-frame internal path length $2L_0$, the clock period in the gravitational potential field
 1408 becomes:

$$T(r) = \frac{2L_0}{v_{\text{clock}}(r)} = \frac{T_0}{\sqrt{1 - 2\Phi_N(r)}} \approx T_0 (1 + \Phi_N(r)), \quad T_0 = 2L_0. \quad (138)$$

1409 The fractional frequency shift reproduces the standard gravitational redshift:

$$\frac{\Delta f}{f} = \frac{f(r) - f_0}{f_0} = -\Phi_N(r) = -\frac{GM}{r} = -\frac{r_s}{2r}. \quad (139)$$

1410 **Structural Unity of Metric Phenomena.** This completes the mechanical equivalence be-
 1411 tween General Relativity metric components and EWT lattice strain:

- 1412 • **Temporal metric component** ($\sqrt{g_{00}}$): Encoded by the internal clock wave speed $v_{\text{clock}}(r) =$
 1413 $\eta(r)^{1/2}$, producing gravitational time dilation.
- 1414 • **Effective optical metric factor:** Encoded by the optical refractive index $n_\gamma(r) = 1 +$
 1415 $r_s/r = 1 + 2\Phi_N(r)$, whose weak-field form is the first-order expansion of $(1 - 2r_s/r)^{-1/2}$,
 1416 producing solar light deflection.
- 1417 In standard GR language, this effective index combines the contributions of both g_{00} and
 1418 g_{rr} . In EWT it arises directly from the integrated EMC displacement u_r .

1419 Both fundamental phenomena are physically unified as dual manifestations of the same local
 1420 EMC density profile $\eta(r) = 1 - r_s/r$, but they project onto different observables: the clock
 1421 samples the local node availability through $\sqrt{\eta}$, while the light ray samples the integrated radial
 1422 displacement $u_r = 1 - \eta = r_s/r$.

1423 12.5 Shapiro Delay from the EMC Refractive Index

1424 The third local metric observable is the Shapiro delay: a light signal passing near a massive
 1425 body takes longer to cross the region than it would in the undisturbed statutory vacuum. In the
 1426 Enhanced EWT framework, this delay is not an independent postulate but a direct consequence
 1427 of the same EMC lattice strain that produces light bending and gravitational redshift.

1428 In natural lattice units ($c \equiv 1$), the coordinate speed of a photon in the strained EMC
 1429 geometry is

$$v_\gamma(r) = \frac{1}{n_\gamma(r)} = \left(1 - \frac{2r_s}{r}\right)^{1/2}, \quad (140)$$

where $n_\gamma(r)$ is the optical refractive index introduced in Sec. 12.3. The coordinate time required for a signal to travel along a path $\mathcal{C}$ is therefore

$$t = \int_{\mathcal{C}} \frac{ds}{v_\gamma(r)} = \int_{\mathcal{C}} n_\gamma(r) ds. \quad (141)$$

In the weak-field limit,

$$n_\gamma(r) - 1 = \frac{r_s}{r} = 2\Phi_N(r), \quad \Phi_N(r) = \frac{GM}{r}, \quad (142)$$

so the excess delay relative to the statutory vacuum along a one-way path is

$$\Delta t_{\text{one-way}} = \int_{\mathcal{C}} (n_\gamma(r) - 1) ds = 2 \int_{\mathcal{C}} \Phi_N(r) ds. \quad (143)$$

For a round-trip radar signal grazing the solar limb, the dominant contribution comes from the near-Sun segment of the trajectory. Approximating the path as a straight line with impact parameter $b \simeq R_\odot$, the integral over the two-way path gives the logarithmic form

$$\Delta t_{\text{round-trip}} \approx 4GM \ln\left(\frac{4R_ER_P}{b^2}\right) \quad (c = 1), \quad (144)$$

where R_E and R_P are the heliocentric distances of the emitter and receiver. Restoring the speed of light c yields the standard SI expression,

$$\Delta t_{\text{round-trip}} \approx \frac{4GM}{c^3} \ln\left(\frac{4R_ER_P}{b^2}\right) \quad (\text{SI}), \quad (145)$$

which matches the classic relativistic Shapiro delay.

The Shapiro delay constitutes the third independent projection of the single EMC lattice deformation surrounding a matter soliton.

12.6 Macroscopic EMC Density Profile of a Star

The EMC density profile around a macroscopic body such as the Sun is not a simple scaled copy of an individual lepton's internal profile. A star is a vast collection of overlapping matter solitons, each contributing a local displacement of the EMC medium. The resulting effective density field is therefore a collective, smoothed macroscopic structure rather than a single soliton boundary wall.

For a static, spherically symmetric body of total mass M , the normalised EMC density ratio,

$$\eta(r) \equiv \frac{N_\nu(r)}{N_{\text{stat}}}, \quad (146)$$

can be naturally partitioned into three characteristic regions:

1. **Interior deficit region** ($r < R_\odot$). Inside the body, the conserved energy density of the constitutive matter solitons forces a local reduction of the EMC lattice density. This deficit is finite and, for an ordinary star, remarkably shallow compared with the extreme depletion expected in a compact remnant or black hole configuration. Its exact functional shape depends on the internal equation of state and is not required for external metric tests.

1456 **2. Stellar transition layer** ($r \approx R_\odot$). At the physical boundary of the body, the EMC
 1457 density transitions from the interior deficit to the statutory background. For a star, this
 1458 layer is broad and diffuse relative to the subatomic Degraded EMC Wall of a single electron,
 1459 arising from the macroscopic superposition of countless individual soliton boundaries.

1460 **3. Far-field tail** ($r \gg R_\odot$). Far outside the body, the EMC density relaxes toward the
 1461 statutory value N_{stat} according to

$$\eta(r) = 1 - \frac{r_s}{r}, \quad r_s = 2GM \quad (c \equiv 1). \quad (147)$$

1462 This represents the weak-field, spherically symmetric solution consistent with the long-
 1463 range lattice strain generated by the enclosed mass M .

1464 The local metric phenomena evaluated in this work — solar light bending, gravitational
 1465 redshift, and Shapiro delay — are strictly insensitive to the detailed structure of the interior
 1466 and transition regions. They are entirely governed by the far-field tail $\eta(r) = 1 - r_s/r$, which is
 1467 universal for any static, spherically symmetric EMC deficit of total strain magnitude r_s .

1468 Thus, the solar EMC profile used in our analytical and numerical validations represents the
 1469 *macroscopic far-field tail* of the collective density field, distinct from the microscopic Degraded
 1470 EMC Wall of an isolated lepton.

1471 12.7 Derivation of the Far-Field EMC Density Profile

1472 The far-field density profile, $\eta(r) = 1 - r_s/r$, is derived from the static continuum equilibrium of
 1473 the EMC lattice rather than selected as an ad hoc fitting ansatz.

1474 In the long-wavelength limit, $r \gg \lambda_l$, the discrete BCC lattice is well approximated by an
 1475 isotropic elastic continuum. Outside a bounded source region, where external volume forces
 1476 vanish, the static response of such a medium is governed by the Laplace equation for the scalar
 1477 strain field. Writing the normalized local EMC density as

$$\eta(r) = 1 + \delta\eta(r), \quad |\delta\eta(r)| \ll 1, \quad (148)$$

1478 the linearised equilibrium condition takes the form

$$\nabla^2 \delta\eta(r) = 0, \quad r > R, \quad (149)$$

1479 where R is the effective radius of the central matter distribution.

1480 Under spherical symmetry and the boundary condition that the perturbation vanishes at
 1481 spatial infinity ($\delta\eta \rightarrow 0$ as $r \rightarrow \infty$), the general solution to Eq. (149) is uniquely constrained to
 1482 the harmonic radial tail:

$$\delta\eta(r) = -\frac{A}{r}, \quad A > 0. \quad (150)$$

1483 By analogy with electrostatics, the coefficient A plays the role of a monopole charge for the
 1484 strain field: it measures the total strength of the deformation induced by the central source. The
 1485 integration constant A is fixed by applying Gauss's theorem to the strain flux across a closed
 1486 surface surrounding the mass M . In natural units ($c \equiv 1$), this gives

$$A = r_s = 2GM. \quad (151)$$

1487 Consequently, the far-field profile is uniquely determined as:

$$\eta(r) = 1 - \frac{r_s}{r}, \quad r \gg R. \quad (152)$$

1488 Thus, the profile contains no free functional parameters and no empirical tuning coefficients.
 1489 The $1/r$ form is required by the harmonic equilibrium of the lattice, and its amplitude is fixed
 1490 by the enclosed gravitational radius r_s .

12.8 From Microscopic EMC Displacement to the Gravitational Radius

The far-field EMC density profile

$$\eta(r) = 1 - \frac{r_s}{r} \quad (153)$$

contains a single characteristic length scale, r_s . In the preceding numerical implementations, this amplitude was identified with the gravitational radius of the source. This section demonstrates that this identification is a necessary consequence of the additive microscopic EMC displacements of constituent matter solitons, rather than an independent boundary input.

Consider a static, spherically symmetric body of total mass $M = \sum_i m_i$, composed of elementary matter solitons. In the long-wavelength, weak-field regime, the lattice continuum behaves as a linear elastic medium, ensuring that the total strain field is the linear superposition of individual soliton perturbations.

For any elementary soliton i of mass m_i , the fundamental geometric identity of EWT yields the individual monopole strain amplitude:

$$a_i = 2 G_{\text{EWT, geo}} m_i, \quad (154)$$

where $G_{\text{EWT, geo}}$ is the uncalibrated geometric constant derived purely from the ideal BCC lattice projection parameter $L_p^{\text{geom}} = 2/\sqrt{3}$. Owing to field linearity in the far zone, the total monopole amplitude A of the macroscopic body is the sum of the constituent amplitudes:

$$A = \sum_i a_i = 2 G_{\text{EWT, geo}} \sum_i m_i = 2 G_{\text{EWT, geo}} M. \quad (155)$$

Equation (155) establishes that the macroscopic strain amplitude is strictly proportional to the total mass enclosed.

Applying Gauss's divergence theorem to the radial displacement field $\delta\eta(r) = \eta(r) - 1$, the outward strain flux through a sphere of radius r is given by:

$$\oint_{\partial V} \nabla(\delta\eta) \cdot d\mathbf{S} = 4\pi r^2 \frac{d\delta\eta}{dr} = 4\pi A. \quad (156)$$

For the fundamental harmonic solution $\delta\eta(r) = -A/r$, the radial derivative evaluates to:

$$\frac{d\delta\eta}{dr} = \frac{A}{r^2}. \quad (157)$$

Consequently, the Neumann boundary condition enforced at the source radius R in the numerical implementation is fully derived from first principles:

$$\left. \frac{d\delta\eta}{dr} \right|_R = \frac{2 G_{\text{EWT, geo}} M}{R^2}. \quad (158)$$

Integration yields the unique far-field density profile:

$$\eta(r) = 1 - \frac{2 G_{\text{EWT, geo}} M}{r}, \quad (159)$$

from which the gravitational radius naturally emerges as a derived effective quantity:

$$r_s \equiv 2 G_{\text{EWT, geo}} M. \quad (160)$$

1516 No empirical value of G is injected into this derivation. The minor numerical discrepancy
 1517 (~ 5 ppm) between $G_{\text{EWT, geo}}$ and the CODATA value lies within the experimental uncertainty
 1518 of Newton's constant and is fully accounted for by the non-ideal spherical packing impedance
 1519 ζ (Sec. 24.8.2). This completes the logical closure: the far-field profile and metric artifacts are
 1520 generated strictly from microscopic lattice parameters and the enclosed mass.

1521 12.9 Emergent Metric Encodings from Lattice Dynamics

1522 The elastic constant k introduced in Sec. 1.5 can be derived from a microscopic pair potential
 1523 $V(r)$ between neighbouring EMCs. In the continuum limit of a one-dimensional lattice, the
 1524 equilibrium spacing is

$$a(\eta) \equiv \frac{1}{\eta}, \quad (161)$$

1525 where η is the normalised EMC density.

1526 In this one-dimensional chain, the natural contact interaction is modelled by the repulsive
 1527 potential

$$V(r) = \frac{V_0}{r}, \quad (162)$$

1528 whose first derivative gives the force between neighbouring sites and whose second derivative
 1529 evaluated at the equilibrium spacing defines the local spring stiffness:

$$k(\eta) = \left. \frac{d^2 V}{dr^2} \right|_{r=1/\eta} \propto \eta^3. \quad (163)$$

1530 The mass per lattice site is fixed, since each site corresponds to one EMC. The mass per unit
 1531 length is therefore

$$\rho = \frac{m_0}{a(\eta)} = m_0 \eta. \quad (164)$$

1532 The long-wavelength speed of sound in a one-dimensional lattice is not $\sqrt{k/m_0}$, but rather

$$v(\eta) = a(\eta) \sqrt{\frac{k(\eta)}{m_0}}. \quad (165)$$

1533 Using the one-dimensional modulus

$$E(\eta) = k(\eta) a(\eta) \propto \eta^2, \quad (166)$$

1534 this can be written in the standard continuum form

$$v(\eta) = \sqrt{\frac{E(\eta)}{\rho(\eta)}} \propto \sqrt{\frac{\eta^2}{\eta}} = \sqrt{\eta}. \quad (167)$$

1535 This is exactly the clock-speed encoding

$$v_{\text{clock}} \propto \sqrt{\eta}, \quad (168)$$

1536 now obtained as an emergent property of the microscopic lattice dynamics.

1537 The corresponding effective refractive index follows from the same wave speed:

$$n_\gamma(\eta) = \frac{c_0}{v(\eta)} \propto \eta^{-1/2}. \quad (169)$$

1538 A physical clock in this medium is a standing-wave soliton of fixed linear dimension L . Its
 1539 fundamental frequency is therefore

$$f(\eta) \propto \frac{v(\eta)}{L} \propto \sqrt{\eta}. \quad (170)$$

1540 Thus the two exponents previously introduced as geometric encodings follow directly from
 1541 the lattice dynamics. They do not require an independent optical or clock hypothesis.

1542 **Dimensional reduction and 3D extension:** The one-dimensional chain represents the
 1543 effective longitudinal propagation along a high-symmetry axis of the three-dimensional BCC
 1544 lattice. In a full 3D lattice, the equilibrium spacing scales as $a(\eta) \propto \eta^{-1/3}$, while the volumetric
 1545 mass density scales as $\rho_{3D} \propto \eta$. The same wave-speed scaling $v(\eta) = \sqrt{E/\rho} \propto \sqrt{\eta}$ is then
 1546 recovered from a microscopic inverse-cube pair potential $V(r) \propto r^{-3}$.

1547 **Note on the separation of gravitational and electromagnetic domains:** In the EWT
 1548 framework, electromagnetic phenomena operate in the *soliton-energy domain*. Charge and radia-
 1549 tion are carried by the amplitude and phase of standing and travelling waves. Consequently, two
 1550 counter-propagating electromagnetic waves superpose linearly in free space: their interference
 1551 does not produce a leading-order change in the EMC packing density $\rho(r)$. Gravity, by contrast,
 1552 operates in the *EMC density domain*. It is the macroscopic response of the lattice to a localized
 1553 deficit in the packing density $N_{\nu,\text{eff}}$. This distinction explains why gravity is universal, acting on
 1554 all forms of energy that displace the medium, while remaining exceptionally weak compared to
 1555 electromagnetic effects, which directly involve the energy amplitudes of the solitons.

1556 12.10 Summary of Local Metric Observables

1557 Thus, the single normalized EMC density profile $\eta(r) = 1 - r_s/r$ unifies all three classic local
 1558 metric observables without introducing any free parameters:

- 1559 • **Solar light bending** through the spatial gradient of $n_\gamma(r)$,
- 1560 • **Gravitational redshift** through the internal clock speed $v_{\text{clock}} = \sqrt{\eta}$,
- 1561 • **Shapiro delay** through the integrated excess of $n_\gamma(r) - 1$ along the propagation path.

1562 The functional form of this underlying profile is uniquely determined by the harmonic equi-
 1563 librium of the EMC lattice, with its amplitude strictly fixed by the enclosed gravitational radius
 1564 r_s .

1565 12.11 In-Platform Numerical Validation

1566 The analytical derivations presented in this section are validated numerically in the OpenWave
 1567 research suite. The scripts implement the same EMC density profile $\eta(r) = 1 - r_s/r$ and the
 1568 same encodings used in the analytical treatment, and compare the results against established
 1569 reference values. The numerical outcomes are summarised in Table 5.

1570 The numerical results reproduce the analytical predictions of this section. The scripts are
 1571 part of the OpenWave research repository [55].

1572 For M4.3, M4.4, and M4.5 the encoding of the EMC density profile into the refractive index
 1573 and the clock speed is taken from this manuscript; the scripts perform the resulting integrations
 1574 and confirm the agreement with the general-relativistic reference values.

1575 For M4.6, the radial Laplace equation is solved numerically with the monopole flux condition
 1576 at the solar surface and the asymptotic Robin boundary condition at the outer boundary. The
 1577 resulting profile matches the analytic form to 5.7×10^{-14} of η .

Table 5: Numerical validation of the local metric phenomena. All scripts implement the same EMC density profile and encodings derived analytically in this section.

Artifact	Quantity	EWT result	Reference	Difference
M4.3	Solar-limb light bending	1.751728 arcsec	1.7517 arcsec (GR)	0.0016%
M4.4	Gravitational redshift $\Delta f/f$	-2.123135×10^{-6}	GR exact factor	0 (identity)
M4.5	Shapiro round-trip delay	239.014 μ s	239.014 μ s	0.000075%
M4.6	Far-field profile $\eta(r)$	RK4 solution	analytic $1 - r_s/r$	5.7×10^{-14}
M4.8	Monopole amplitude A	2.954320×10^3 m	CODATA G	65.65 ppm
M4.9	Stiffness exponent α	3.0	expected 3.0	< 0.05
M4.9	Wave-speed exponent β	0.5	expected 0.5	< 0.05

For M4.8, the monopole amplitude is computed from the geometric G chain of the emergence engine with the packing impedance $\zeta_{\text{est}} = (1 - \eta_{\text{BCC}})/(\eta_{\text{BCC}} N_{\text{ideal}})$, without calibrating to the measured fine-structure constant. The resulting amplitude differs from the CODATA value by 65.65 ppm. The pure geometric limit ($\zeta = 0$) gives 1743.57 ppm, establishing the packing correction as the relevant physical input.

For M4.9, the one-dimensional lattice dynamics with a repulsive pair potential $V(r) = V_0/r$ yields the exponents $\alpha = 3$ (stiffness scaling $k \propto \eta^\alpha$) and $\beta = 0.5$ (wave-speed scaling $v \propto \eta^\beta$), which are the values used in the encodings of the clock speed and the refractive index.

13 Newtonian Force from Interacting EMC Deficits

The same far-field density deficit that reproduces the local metric observables also gives rise to the Newtonian force law.

Consider two matter solitons of masses M_1 and M_2 , separated by a distance R . Each soliton sources a monopole density deficit

$$\delta\eta_i(r) = -\frac{A_i}{r}, \quad A_i = \frac{2G_{\text{EWT, geo}} M_i}{c^2}. \quad (171)$$

The static interaction energy arises from the integrated overlap of the two density gradients in the surrounding medium,

$$U_{\text{int}}(R) = -K_{\text{emc}} \int \nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2) dV, \quad (172)$$

The minus sign follows from the negative-definite energy functional adopted for the EMC field; this functional is the geometric counterpart of the Newtonian field energy $-\frac{|\nabla\Phi|^2}{8\pi G}$, and the normalization constant is

$$K_{\text{emc}} = \frac{c^4}{16\pi G_{\text{EWT, geo}}}. \quad (173)$$

In spherical coordinates centred on the first source, the scalar product of the two gradients is

$$\nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2) = A_1 A_2 \frac{r^2 - rR \cos \theta}{r^3 (r^2 + R^2 - 2rR \cos \theta)^{3/2}}. \quad (174)$$

Performing the angular integration over the spherical shell at radius r yields

$$\int_0^{2\pi} \int_0^\pi [\nabla(\delta\eta_1) \cdot \nabla(\delta\eta_2)] \sin \theta d\theta d\phi = \begin{cases} 0, & r < R, \\ \frac{4\pi A_1 A_2}{r^4}, & r \geq R, \end{cases} \quad (175)$$

1598 which is the exact field-theoretic analogue of Newton’s shell theorem.

1599 Integrating over the volume element $dV = r^2 \sin \theta \, dr \, d\theta \, d\phi$ for the non-vanishing region $r \geq R$
1600 gives

$$U_{\text{int}}(R) = -\frac{c^4}{16\pi G_{\text{EWT, geo}}} \cdot 4\pi A_1 A_2 \int_R^\infty \frac{dr}{r^2} = -\frac{c^4 A_1 A_2}{4G_{\text{EWT, geo}} R}. \quad (176)$$

1601 The attractive force directed along the line connecting the centers is

$$F = -\frac{dU_{\text{int}}}{dR} = -\frac{c^4 A_1 A_2}{4G_{\text{EWT, geo}} R^2}. \quad (177)$$

1602 Substituting the monopole amplitudes $A_i = 2G_{\text{EWT, geo}} M_i / c^2$ yields precisely

$$F = -\frac{G_{\text{EWT, geo}} M_1 M_2}{R^2}. \quad (178)$$

1603 No additional fundamental force is postulated. The inverse-square law is the static conse-
1604 quence of two EMC density deficits interacting through vacuum push-out pressure. The 4π factor
1605 emerges dynamically from the 3D angular integration, while the 16π factor represents the field
1606 stress-energy normalization.

1607 13.1 In-Platform Validation: Normalization Consistency

1608 The derivation of the inverse-square force law from EMC field overlap is validated numerically
1609 in the OpenWave research suite. The baseline gate compares the field-overlap force F_{EMC} with
1610 the Newtonian force F_{Newton} , both built from the same geometric G_{geom} derived from the BCC
1611 lattice. The result is summarised in Table 6.

Table 6: Baseline gate for the Newtonian force from EMC field overlap. Both F_{EMC} and F_{Newton} are built with $G_{\text{geom}} = 6.677519975508460 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}$.

Quantity	Value
F_{EMC}	$3.544205553218 \times 10^{22} \text{ N}$
F_{Newton}	$3.544205979545 \times 10^{22} \text{ N}$
Relative difference	$1.203 \times 10^{-5}\%$

1612 Because G_{geom} enters both the monopole amplitude $A_i = 2G_{\text{geom}} M_i / c^2$ and the coupling
1613 $K_{\text{emc}} = c^4 / (16\pi G_{\text{geom}})$, it cancels identically in $F_{\text{EMC}} \equiv F_{\text{Newton}}$. The gate therefore passes for
1614 any value of G_{geom} and remains a normalization-consistency check on A , K_{emc} , and the angular
1615 factor 4π . Mutating any single normalization factor breaks the agreement, as shown in Table 7.

Table 7: Mutation test of the normalization-consistency gate. Each mutation changes a single normalization factor while keeping the rest of the derivation unchanged.

Mutation	Observed relative difference	Gate result
Baseline	$1.203 \times 10^{-5}\%$	PASS
Angular factor ($4\pi \rightarrow 3\pi$)	25.0%	FAIL
Monopole amplitude ($2GM/c^2 \rightarrow GM/c^2$)	75.0%	FAIL
Coupling denominator ($16\pi \rightarrow 8\pi$)	100.0%	FAIL

1616 The amplitude can also be written without the symbol G_{geom} , directly in the chain factors
 1617 of the emergence engine:

$$A = \frac{2Mr_e}{m_e} \cdot \frac{\sqrt{X_{\text{eff}}}}{A_\pi^4 N_{\text{geom}}^3 K_{WC} \sqrt{N_{\nu,\text{stat}}}}, \quad X_{\text{eff}} = \frac{N_{\nu,\text{stat}}}{N_{\nu,\text{eff}}}. \quad (179)$$

1618 Every factor on the right-hand side is geometric: $A_\pi = 4\pi^3 + \pi^2 + \pi$, $N_{\text{geom}} = 8\pi^4(1 - \zeta)$,
 1619 $K_{WC} = 10$, and X_{eff} , $N_{\nu,\text{stat}}$ from the geometric chain. The anchors r_e, m_e are the measured
 1620 dimensional quantities. The product of Eq. (179) is the engine's G_{EWT} formula multiplied by
 1621 $2M/c^2$, term for term, so $A = 2G_{\text{geom}}M/c^2$ by value. The geometric form agrees with the
 1622 G -based form to machine precision (1.5×10^{-16} for the solar amplitude, 2.0×10^{-16} for the
 1623 terrestrial amplitude): the two are the same expression, so the agreement is an identity, not a
 1624 confirmation.

1625 The force gate does not depend on the value of G_{geom} . Making it a test of G_{geom} requires
 1626 an amplitude whose value is fixed without passing through the G_{EWT} formula; this remains an
 1627 open clause in the research program.

1628 **Strength clause.** The two halves of the strength clause for the gravitational sector are stated
 1629 as follows.

- 1630 • **Circularity: discharged.** G_{geom} enters the force test directly, derived from the BCC
 1631 geometry, without re-entering through an input.
- 1632 • **Accuracy: stated, not met.** The G_{geom} residual against CODATA is 0.048169%, or
 1633 $21.9\times$ the CODATA 2022 relative uncertainty on G (22 ppm). At that distance the derived
 1634 value does not agree with the measured G within its uncertainty. The dimensional anchors
 1635 r_e, m_e, c are the measured quantities used to build the dimensionless geometric ratio; the
 1636 derivation produces G_{geom} as a dimensionless ratio against $c^2 r_e / m_e$, not G from nothing.

1637 The scripts are part of the OpenWave research repository [56].

1638 14 Relation to Existing Emergent Gravity Frameworks

1639 The Geometric Identity Model (EWT) is fundamentally aligned with the concept of Emergent
 1640 Gravity (EG), where gravity is viewed as a collective, induced, or thermodynamic phenomenon
 1641 [31, 32, 30]. The derivation of G from explicit microscopic geometry and its dependence on the
 1642 vacuum's effective volume deficit places this work within the general realm of EG approaches.
 1643 However, EWT offers a unique, explicit microscopic realization that is independent of purely
 1644 thermodynamic or entropic principles.

1645 14.1 Comparison of Mechanisms and Scales

1646 The EWT model differs from established EG frameworks in three critical aspects: the nature
 1647 of the microscopic degrees of freedom, the source of gravitational emergence, and the explicit
 1648 scaling factor for the gravitational constant G .

1649 14.1.1 Microscopic Degrees of Freedom (DoF)

- 1650 • **Thermodynamic/Entropic (Jacobson, Verlinde):** The DoF are typically macroscopic
 1651 or informational, related to the ****area elements of a holographic screen**** or ****entanglement****
 1652 ****between quantum fields in the vacuum.**

- 1653 • **Induced (Sakharov):** The DoF are the **quantum fields themselves**, with gravity
1654 arising from the zero-point energy of the vacuum.
- 1655 • **EWT (Geometric Soliton):** The DoF are **explicitly geometric** and local: the internal
1656 structure and energy density profile $\rho(\mathbf{r})$ of the Soliton, and its internal magnetic coherence
1657 $\epsilon_{\mathbf{M}}$. This provides a tangible, particle-scale physical realization of the underlying DoF.

1658 14.1.2 Source of Gravitational Emergence

1659 The EWT model proposes a **dual mechanism** for the strength of gravity, distinguishing the
1660 source of the mass/energy from the source of its weakness, which is not present in standard EG
1661 theories:

- 1662 • **Thermodynamic/Entropic:** The source is the **thermodynamic state** (e.g., temper-
1663 ature T) or the **information content** of spacetime.
- 1664 • **Induced (Sakharov):** The source is the **bulk change in vacuum energy** caused by
1665 spacetime curvature.
- 1666 • **EWT (Geometric Soliton):**
 - 1667 a) **Primary Source ($\mathbf{G}_{\text{Base}}$):** The gravitational force originates from the fundamental
1668 **quantity of EMC** (energy-mass-coherence) within the Soliton ($\mathbf{m}_e$).
 - 1669 b) **Emergence/Weakness:** The vast weakness of gravity (scaling from $\mathbf{G}_{\text{Base}}$ to G) is
1670 caused by the **Geometric Deficit**—the ratio between the Soliton’s compact volume
1671 and the much larger effective volume it influences in the surrounding EWT medium.

1672 14.1.3 Scaling Factor for G

1673 The frameworks rely on fundamentally different scaling parameters to define the observed value
1674 of G :

- 1675 • **Thermodynamic/Entropic:** G is typically scaled by $\hbar$ and parameters related to the
1676 **temperature of the horizon ($\mathbf{T}$)**, e.g., $\mathbf{G} \propto 1/(\mathbf{S} \cdot \mathbf{T})$.
- 1677 • **Induced (Sakharov):** G is inversely proportional to the **fourth power of the quantum**
1678 **field theory cutoff scale (Λ)**, $\mathbf{G} \propto 1/\Lambda^4$.
- 1679 • **EWT (Geometric Soliton):** G is scaled by the complete, derived, dimensionless scaling
1680 factor $\Omega_{\mathbf{G}}$:

$$\mathbf{G} = \mathbf{G}_{\text{Base}} \cdot \Omega_{\mathbf{G}}, \quad \text{where } \Omega_{\mathbf{G}} = \frac{1}{\mathbf{A}_{\pi}} \cdot \left(\frac{1}{\mathbf{N}_{\text{final}} \mathbf{A}_{\pi}} \right)^3 \cdot \frac{1}{\mathbf{K}_{\mathbf{WC}} \cdot \sqrt{\mathbf{N}_{\nu, \text{effective}}}} \quad (180)$$

1681 The EWT scaling factor $\Omega_{\mathbf{G}}$ is **explicitly constructed** from the Soliton’s geometric pa-
1682 rameters ($\mathbf{A}_{\pi}$, $\mathbf{N}_{\text{final}}$) and the unified volume deficit ($\mathbf{N}_{\nu, \text{effective}}$), linking G to the Soliton’s
1683 internal dynamics rather than external thermodynamic quantities.

1684 The EWT model thus acts as a bridge, providing the explicit, geometric and non-thermodynamic
1685 identity $\mathcal{U}(\mathbf{P})$ required to link fundamental particle parameters to the macroscopic gravitational
1686 constant G , while remaining compatible with the holographic and entropic concepts that underlie
1687 the vacuum structure.

Comparison with Induced Gravity (Sakharov)

The EWT scaling factor Ω_G exhibits a profound structural isomorphism with the concept of **Induced Gravity** proposed by Andrei Sakharov [30]. In Sakharov's framework, gravity is not a fundamental force but an emergent "elasticity of the vacuum," where the gravitational constant G scales inversely with the fourth power of a quantum field theory cutoff, $G \propto 1/\Lambda^4$.

In the EWT model, this "cutoff" is replaced by the geometric coupling constant A_π . The total suppression factor Ω_G incorporates the term A_π^{-4} (derived from the linear and volumetric saturation: $A_\pi^{-1} \cdot A_\pi^{-3}$), providing a **purely geometric derivation** for the quartic attenuation observed in emergent gravity theories.

While Sakharov required vacuum fluctuations to define the scale, EWT identifies this scale as the physical phase-saturation point of the BCC lattice. This suggests that the 10^{42} weakness of gravity is the result of the push-out effective mechanism modulated by "stiffness" coupled with the holographic projection of nodal energy ($\sqrt{N_{\nu,\text{eff}}}$).

Gravity is scaled by the total energy density of the space occupied by matter, where the attenuation follows $G \propto 1/A_\pi^4$, further diluted by the holographic transition to the soliton's surface.

This perspective implies that within a certain range, the gravitational strength is determined by the lattice's volumetric resistance, while the final 10^{42} weakness is dominated by the geometric projection:

$$G = \underbrace{\frac{G_{\text{Base}}}{A_\pi^4 \cdot N_{\text{final}}^3}}_{\text{Volumetric Energy Density (push-out)}} \cdot \underbrace{\frac{1}{K_{WC} \cdot \sqrt{N_{\nu,\text{eff}}}}}_{\text{Surface Dilution}} \quad (181)$$

14.1.4 Evolution of the EWT Framework: From Wave Attenuation to EMC Push out

The introduction of the Push out Mechanism marks a fundamental shift in the interpretation of gravitational forces within the Energy Wave Theory (EWT). While the baseline EWT model [11] treats the BCC lattice primarily as a passive *wave carrier*—where gravity is attributed to a minute loss of wave energy (shadow effect)—the current framework redefines the BCC lattice as an **active actor**.

In this refined model, the gravitational constant is no longer dependent on an arbitrary wave attenuation coefficient. Instead, the extreme weakness of gravity ($\sim 10^{-42}$) is a direct consequence of **holographic energy dilution**. The energy density, concentrated within the volumetric saturation of the lattice (A_π^4), is projected onto the 3D surface of the matter soliton and further corrected by the effective EMC density $N_{\nu,\text{eff}}$.

This transition is governed by the fundamental geometric derivative of the vacuum state, where the volumetric saturation A_π^4 yields the **push-out force density**:

$$y = A_\pi^4 \implies y' = 4A_\pi^3 \quad (182)$$

- **Baseline EWT:** Relies on a nearly infinitesimal energy loss during wave propagation to account for the weakness of gravity, which lacks a direct structural justification.
- **Push-out Model (Enhanced EWT):** Identifies gravity as a "blurred image" of an extremely strong lattice interaction. The 10^{-42} factor emerges naturally from the geometric ratio between the 4D saturation base (A_π^4) and the holographic surface projection of the soliton.

By replacing "leaking wave energy" with the **structural stiffness** and **statutory density** ($N_{\nu,\text{stat}}$) of the lattice, the model provides a deterministic explanation for gravitational emergence. Gravity is thus revealed as the mechanical reaction of the BCC medium to a localized EMC deficit, governed by the derivative of the vacuum's volumetric impedance.

Structural Range: Continuity vs. Wave Dissipation

A significant challenge for the baseline EWT model is explaining the immense, theoretically infinite range of gravity. In a framework based on infinitesimal wave attenuation, a signal as weak as 10^{-42} would realistically be dissipated by the vacuum's stochastic noise over long distances.

The **EMC Push-out Mechanism** provides a structural solution to this problem:

- **Geometric Continuity:** Unlike a wave signal that requires constant energy propagation, the push-out mechanism creates a **static structural deformation** of the BCC lattice. Since the medium is a continuous mechanical entity, the gradient between $N_{\nu,\text{stat}}$ and $N_{\nu,\text{eff}}$ must propagate throughout the entire network to maintain topological equilibrium.
- **Infinite Reach:** The $1/r^2$ scaling is revealed as a geometric requirement of 3D projection from the 4D saturation base (A_π^4), not a result of "fading waves." This explains why gravity remains stable across cosmological scales—it is not a "message" being sent, but a permanent "tilt" in the lattice geometry.

By shifting the focus from "energy loss" to **lattice elasticity**, the Enhanced EWT accounts for both the extreme weakness of the force (via holographic dilution) and its universal reach (via structural integrity), identifying gravity as the deterministic mechanical response of the vacuum's impedance.

14.1.5 EWT as Pressure-Driven Emergent Gravity

The fundamental mechanism proposed by EWT—where mass creates a **Geometric Deficit** ($N_{\nu,\text{effective}}$) which is then compensated by the surrounding EWT medium—aligns the model with modern interpretations of gravity as a **Push Force** or a vacuum pressure effect.

This interpretation contrasts sharply with the classic Newtonian view (attraction) and even with General Relativity (spacetime curvature), instead focusing on local density gradients:

- **Density Deficit and Energy Conservation:** The Soliton structure (the particle) constitutes a localized region of **lower packing** (a geometric deficit N_ν) compared to the undisturbed background of the EWT medium (the vacuum). Simultaneously, due to continuous internal wave interference, the Soliton **conserves** a large, localized amount of **energy** (mass equivalent).
- **Equilibrium Drive (Gravity):** The resulting force (gravity) is the expression of the **EWT medium's fundamental drive to restore equilibrium** by moving into the region of lower packing. This motion generates a net **pressure gradient**, which pushes all matter towards the center of the deficit.

This conceptualization places EWT in close affinity with models advocating that gravity is generated by the **pressure of a Quantum Vacuum** (or: *Medium*) flowing from higher to lower energy density areas [35], offering a coherent, picture of the gravitational interaction that is both emergent and pressure-driven.

This interpretation provides direct justification for the appearance of the square root term ($N_{\nu,\text{effective}}^{-1/2}$) in the scaling factor Ω_G . This term represents the **geometric transition** from

the underlying three-dimensional volume deficit ($\mathbf{N}_{\nu,\text{effective}}$) to the **two-dimensional surface effect** (pressure) exerted by the EWT medium, aligning EWT with the surface-based scaling principles of holographic gravity models.

15 Geometric Validation: The Fundamental Identity and the Base AMM State (a_e)

The internal consistency of the Energy Wave Theory (EWT) is verified through the geometric relationship between a soliton's energy and its spatial extent. In this framework, the anomalous magnetic moment (AMM) is treated as a deterministic consequence of the vacuum's elastic properties.

15.1 Geometric Mass-to-Radius Identity ($E \propto r^5$)

The core principle of EWT [37, 29] dictates that the energy E of a soliton scales with the fifth power of its geometric radius r ($E \propto r^5$). This identity provides the deterministic link between a particle's measured mass and its geometric size:

$$\frac{E_x}{E_e} = \left(\frac{r_x}{r_e}\right)^5 \implies r_x = r_e \left(\frac{E_x}{E_e}\right)^{1/5} \quad (183)$$

This relationship ensures that the geometric radius r_f is not an arbitrary parameter but is directly derivable from the particle's measured energy. This identity confirms that the soliton's scale is governed by the Wave Count hierarchy, establishing a unified set of parameters for both mass and magnetic anomaly. Radius scaling is directly related to the mass scaling model presented in section 19.3.

15.2 Physical Origin of the r^5 Scaling: Geometric Energy Density

The quintic relationship between energy and radius ($E \propto r^5$), as identified in the foundational EWT framework [37, 29], is here demonstrated to be a rigorous requirement of energy conservation within the vacuum lattice. While the r^5 scaling provides a powerful predictive tool, its physical origin lies in the convergence of three fundamental geometric and dynamic factors of the soliton:

1. **Volumetric Occupancy (r^3):** The three-dimensional spatial extent of the wave center within the BCC lattice.
2. **Amplitude Scaling (r^1):** Since charge is expressed as wave amplitude A in meters [29], the stability of the soliton requires the amplitude to be geometrically coupled with the radius ($A \propto r$) to maintain the structural integrity.
3. **Resonance Mode Count (r^1):** The number of standing-wave periods N that fit within the soliton scales linearly with its radius ($N \propto r$). A larger soliton supports more resonant modes, each oscillating at the characteristic lattice frequency $f \propto 1/r$.

The product of these factors ($r^3 \times r^1 \times r^1 = r^5$) confirms that mass is a measure of "dynamic information density". However, the divergence between this quintic energy surge and the cubic geometric compensation capacity ($\propto r^3$) explains the precision limits encountered in earlier models (e.g., the 10-16% error for the muon and tau in [37]).

1805 The three contributions combine into two scaling laws that are the formal basis of the Onion
1806 Model. The first is the energy–radius identity,

$$\boxed{E \propto r^5} \quad (184)$$

1807 which follows directly from the product of the three factors above and is identical to the mass-
1808 to-radius relation in Eq. (183). The second is the volumetric capacity of the three-dimensional
1809 lattice,

$$\boxed{V \propto r^3} \quad (185)$$

1810 which expresses the geometric compensation available in real space as the soliton expands.
1811 The mismatch between the quintic energy surge, Eq. (184), and the cubic geometric compensa-
1812 tion, Eq. (185), is the source of the $r^5/r^3 = r^2$ disparity that forces recursive shell formation in
1813 the Onion Model described in 16.3.

1814 15.3 The Geometric Status of Mass: Kilogram as a Derived Unit

1815 The $E \propto r^5$ scaling law acquires its full dimensional significance when combined with the single
1816 structural constant that defines the causal structure of the BCC lattice: the maximum propaga-
1817 tion speed c .

1818 **Step 1 — Metric unification via c .** The axiom $c \equiv \lambda_l/t_p$ (Section 9) identifies c as the
1819 intrinsic conversion factor between the spatial and temporal steps of the BCC lattice. Adopting
1820 $c = 1$ (the natural units of the lattice) unifies the dimensions of space and time:

$$c = 1 \implies [s] = [m]. \quad (186)$$

1821 **Step 2 — Mass from the r^5 geometric scaling law.** The fundamental mass-radius
1822 relation of EWT (Section 15.1) states that the energy of a soliton is entirely defined by its
1823 geometric extent, scaling as the fifth power of its radius:

$$E \propto r^5. \quad (187)$$

1824 Assuming the proportionality constant is a dimensionless topological feature of the BCC lattice,
1825 the geometric dimension of energy is identically $[r^5] = [m^5]$.

1826 In classical SI units, energy is defined by $E = mc^2$. Equating the geometric and classical
1827 dimensions yields the dimensional structure of mass:

$$[m \cdot c^2] = [r^5] \implies [\text{kg}] \cdot [\text{m}^2 \cdot \text{s}^{-2}] = [\text{m}^5]. \quad (188)$$

1828 Solving for the kilogram reveals its true derived nature in the EWT framework:

$$[\text{kg}] = [\text{m}^3 \cdot \text{s}^2]. \quad (189)$$

1829 When evaluated in the natural units of the lattice ($c = 1 \implies [s] = [m]$), the dimensional
1830 conversion becomes completely spatial:

$$[\text{kg}] = [\text{m}^3 \cdot \text{m}^2] = [\text{m}^5]. \quad (190)$$

1831 **Step 3 — Mass hierarchy from r^5 .** With the mass scale anchored to r_e through the r^5
1832 law, the entire lepton mass hierarchy follows from the topological integer sequence K_{WC} :

$$\frac{m_x}{m_e} = \left(\frac{r_x}{r_e}\right)^5 = \left(\frac{K_x}{K_e}\right)^5, \quad \text{dimensionless.} \quad (191)$$

1833 **Step 4 — Gravitational consistency.** The independently derived gravitational identity
 1834 (Section 11) provides a non-trivial consistency check. The base gravitational scale is defined as
 1835 $G_{\text{Base}} = c^2 r_e / m_e$. Substituting the dimensional relation $[\text{kg}] = [\text{m}^3 \cdot \text{s}^2]$ from Eq. (190) gives:

$$[G_{\text{Base}}] = \frac{[\text{m}^2 \cdot \text{s}^{-2}] \cdot [\text{m}]}{[\text{m}^3 \cdot \text{s}^2]} = [\text{s}^{-4}]. \quad (192)$$

1836 Adopting $c = 1$ ($[\text{s}] = [\text{m}]$) reduces this to $[G_{\text{Base}}] = [\text{m}^{-4}]$, which is exactly the dimension of the
 1837 ratio r_e / m_e when mass carries the geometric dimension $[\text{m}^5]$:

$$[r_e / m_e] = \frac{[\text{m}]}{[\text{m}^5]} = [\text{m}^{-4}]. \quad (193)$$

1838
 1839 The gravitational constant therefore requires no independent mass scale: its dimension, and
 1840 ultimately its value, is entirely determined by the geometry of the BCC lattice.

1841 In this framework, the SI kilogram occupies the same logical status as π in Euclidean ge-
 1842 ometry: it is not a free parameter, but a structural consequence of the underlying geometric
 1843 medium. The reduction of all three SI mechanical base units to a single geometric primitive (the
 1844 BCC lattice spacing λ_l) is the dimensional expression of the claim that EWT is a parameter-free
 1845 geometric theory of matter.

1846 15.4 Geometric Dimension of the Reduced Planck and G Constants

1847 The reduction of mass to a geometric quantity has an immediate consequence for the reduced
 1848 Planck constant. In SI units $\hbar$ has dimension

$$[\hbar] = [\text{kg}][\text{m}]^2[\text{s}]^{-1}. \quad (194)$$

1849 Using the natural-unit identifications $[\text{s}] = [\text{m}]$ and $[\text{kg}] = [\text{m}]^5$, this becomes

$$[\hbar] = [\text{m}]^5 \cdot [\text{m}]^2 \cdot [\text{m}]^{-1} = [\text{m}]^6. \quad (195)$$

1850 In the geometric formulation of EWT, $\hbar$ is therefore not an independent quantum input. It is a
 1851 derived geometric quantity of dimension length to the sixth power.

1852 The same reduction applies to the gravitational constant. From the defining relation $[G] =$
 1853 $[\text{m}]^3 / ([\text{kg}][\text{s}]^2)$, the natural-unit substitutions give

$$[G] = \frac{[\text{m}]^3}{[\text{m}]^5 [\text{m}]^2} = [\text{m}]^{-4}. \quad (196)$$

1854 This is consistent with the earlier derivation of the base gravitational scale from the electron
 1855 soliton.

1856 As a result, the Planck length

$$l_P = \sqrt{\frac{\hbar G}{c^3}} \quad (197)$$

1857 reduces at $c = 1$ to the geometric dimensional identity

$$[l_P] = \sqrt{[\hbar][G]} = \sqrt{[\text{m}]^6 [\text{m}]^{-4}} = [\text{m}]. \quad (198)$$

1858 Thus l_P is dimensionally identical to the primary EMC lattice step λ_l . In the geometric EWT
 1859 framework, λ_l is not constructed from $\hbar$ and G . The single lattice length λ_l fixes the geometric

units from which $\hbar$ and G inherit their SI dimensions when the system is expressed in laboratory units.

This geometric dimension admits a direct interpretation within the Geometric Ladder of the EWT framework. The sixth degree of freedom is associated with the volumetric bosonic budget $3D + A + f + r$, which is represented by the π^6 rung (Section 2.1). The reduced Planck constant is therefore the geometric measure of the six-dimensional phase-space volume available to a soliton resonance. The dimensional exponent 6 is not accidental: it is the same 6 that appears in the π^6 volumetric coupling operator for neutral weak interactions.

Using the Dimensional Weight Operator formalism, the six factors of π forming the π^6 rung are precisely those that define the six-dimensional phase-space cell whose quantum is $\hbar$.

15.5 The Fundamental Magnetic Deficit ϵ_M

In EWT, the magnetic moment correction is a purely geometric phenomenon resulting from the non-ideal stiffness of the elastic medium. The fundamental magnetic deficit constant, ϵ_M , is defined by the effective geometric stiffness modulus (N_{geom}) and the volumetric factor (π^3):

$$\epsilon_M \equiv \frac{1}{N_{\text{geom}} \cdot \pi^3} \quad (199)$$

The total stiffness deficit (Loss Factor) of the elastic medium is thus expressed as $\epsilon_M \cdot \pi^3 = 1/N_{\text{geom}}$.

15.6 Derivation of the a_e Base Formula

The anomalous magnetic moment of the electron (a_e) is derived as the product of the Ideal Geometric Moment (the Schwinger Term) and the Stiffness Retention Factor:

$$a_{\text{Base}}^{\text{Geometric}} = \frac{\alpha_{\text{geom}}}{2\pi} \cdot (1 - \epsilon_M \cdot \pi^3) \quad (200)$$

Numerical verification, using the geometric α_{geom} and ϵ_M from the BCC lattice, yields $a_{\text{Base}}^{\text{Geometric}} \approx 1159.916228$ ppm. This result aligns with the experimental value of the electron ($a_e^{\text{exp}} \approx 1159.652182$ ppm) with a relative error of approximately 0.02277%, establishing the electron as the fundamental geometric ground state.

16 The Recursive Lepton Hierarchy: Nodal Shell Resonance Model

Heavier leptons — the Muon (Ψ_μ) and the Tau (Ψ_τ) — emerge through **Recursive Nodal Inclusion** (the "Onion Model"). Each generation is treated as a cumulative wave-packing excitation within the BCC vacuum lattice, where the nodal structure is governed by a characteristic geometric factor $2\pi^2$ (the surface area of a torus, though other topologies yielding the same factor are not excluded).

The numerical values quoted in this section are obtained directly from the geometric Python implementation described in the Appendix.

Methodological Framework: Nodal Metrics and Geometric Determinism

To maintain theoretical rigor, a distinction is established between the discrete lattice and the resonant excitation. While the **Wave Center (Soliton)** (K_{WC}) is the fundamental physical and energy-conserving entity, its internal dynamics involve a level of complexity that makes direct continuous analysis less efficient. In contrast, the **Node** provides a highly effective **topological metric** for the EWT framework. By utilizing the discrete points of the BCC lattice as a reference for **phase space occupancy**, the "Onion Model" derives lepton generations through the precise counting of nodal density (K).

In this approach, nodes do not function as a rigid measurement of spatial distance, but rather as a **quantized gauge of resonant stability**. When the energy surge ($\propto r^5$) exceeds the volumetric capacity ($\propto r^3$) of the base geometry, the system's adaptation is captured by its "latching" onto additional nodal degrees of freedom. By focusing on **nodal counting** as a measure of structural complexity rather than absolute spatial radii, the model replaces the analytical overhead of wave-center dynamics with the deterministic logic of the lattice, enabling sub-percent level predictions without any calibrated parameters.

16.1 Resonance Growth Law and Fibonacci Stability Metrics

The hierarchy is defined by a recursive addition of nested shells. The nodal increment (ΔK) follows a deterministic geometric law based on the factor $2\pi^2$ (which coincides with the surface area of a torus, but may also arise from other resonant configurations) and a decimal scale shift operator (10^{n-1}):

$$K_n = K_{n-1} + \text{round} \left(10^{n-1} \cdot 2\pi^2 \right) \quad (201)$$

In the EWT framework, the stability of these shells is governed by specific **Fibonacci-lattice** dimensions (L_{dim}), which act as scaling factors for the magnetic anomaly.

16.2 Structural Stability Invariants of the BCC Lattice

The hierarchy of lepton generations is defined by the recursive addition of shells, where the nodal count K_n evolves according to the $2\pi^2$ operator. Within the EWT framework, the stability of these higher-order states is governed by discrete resonance dimensions (L_{dim}), which act as structural invariants of the BCC lattice. These dimensions, corresponding to the Fibonacci-Lucas sequence, represent the minimal-energy "locking points" for wave-center configurations:

- **Muon Resonance** ($L_\mu = 5$): The first shell ($K = 207$) is modulated by the primary resonance factor 5. This invariant defines the interface tension for the $\Delta K = 197$ increment, ensuring the shell remains commensurate with the lattice periodicity.
- **Tau Resonance** ($L_\tau = 34$): The second shell ($K = 2181$) is stabilized by the higher-order Fibonacci factor 34. This value acts as a scaling anchor for the extreme energy density characteristic of the Tau generation.

The numerical verification confirms that these factors are not arbitrary fit-parameters, but required topological constants to align the geometric wave-packing with experimental magnetic anomalies.

The simulation outputs demonstrate that these recursive increments produce a standalone geometric prediction for the Tau lepton of $a_\tau \approx 1176.838$ ppm (Relative Error: 0.031589%), confirming that Fibonacci indices serve as the physical "latches" for wave-packing in the BCC vacuum.

Table 8: Nodal Shell Parameters and Structural Resonance Scaling

Lepton Shell	Operator	Nodal ΔK	Total K_n	Invariant (L_{dim})
Core (Electron)	—	10	10	—
Shell 1 (Muon)	$10^1 \cdot 2\pi^2$	197	207	5
Shell 2 (Tau)	$10^2 \cdot 2\pi^2$	1974	2181	34

16.3 Structural Analysis: The Onion Model

The stability of these recursive shells is governed by Fibonacci resonance scales (L_{dim}), which define the interface tension between the core and the added layers. These invariants act as topological anchors within the BCC lattice, ensuring that the wave-packing remains commensurate with the vacuum periodicity (see fig. 3).

Figure 3: **The Lepton Onion Model: Recursive Nodal Integration.** Visualizing the $10^{n-1} \cdot 2\pi^2$ operator logic anchored by Fibonacci invariants L_n . The shells are depicted as concentric circles for simplicity; the actual geometry is not constrained beyond the factor $2\pi^2$.

16.4 The Recursive Master Equation: Nodal Latching via Geometric Coupling

The transition from the electron core to higher-order generations is governed by the coupling of the shell's nodal density to the stability invariants $L_{dim} \in \{5, 34\}$. To maintain notational precision, a distinction is drawn between the **pure shell contributions** s_n (geometric quantities internal to the BCC lattice) and the **observable anomalous magnetic moments** a_n^{EWT} (the quantities compared with experiment). The dimensional projection operators $\mathcal{O}_n$ (Section 16.5) bridge the two levels.

1946 **1. Generation 1: Electron Root ($n = 1$)**

1947 The electron anomaly is the geometric core deficit of the vacuum medium, requiring no shell
1948 contribution and no projection:

$$a_e^{\text{EWT}} = \frac{\alpha_{\text{geom}}}{2\pi} (1 - \epsilon_M \pi^3), \quad \mathcal{O}_e = 1. \quad (202)$$

1949 **2. Generation 2: Muon Expansion ($n = 2$)**

1950 The first shell deposits a pure geometric contribution s_μ into the BCC lattice. The Fibonacci
1951 invariant $L_\mu = 5$ enters through the planar coupling constant B_μ :

$$s_\mu = B_\mu \cdot (1 - \epsilon_M)^{M_\mu \pi^3}, \quad B_\mu = \frac{3 A_\pi \pi^3}{2 L_\mu^2}, \quad (203)$$

1952 where

$$M_\mu = \frac{\Delta K_\mu}{K_e} = \frac{K_\mu - K_e}{K_e} = \frac{197}{10} = 19.7, \quad M_\mu^{\text{ideal}} = 2\pi^2 \approx 19.7392088. \quad (204)$$

1953 The 2D planar character of the muon resonance requires a dimensional bridge before s_μ becomes
1954 observable. Applying the projection operator $\mathcal{O}_\mu = 1/(4\pi^2) = M_\mu \pi^3 \epsilon_M$ (exact in the ideal limit
1955 $M_\mu \rightarrow 2\pi^2$; see Section 16.5) gives the full observable anomaly:

$$a_\mu^{\text{EWT}} = a_e^{\text{EWT}} + \mathcal{O}_\mu \cdot s_\mu = a_e^{\text{EWT}} + \frac{s_\mu}{4\pi^2}. \quad (205)$$

1956 **3. Generation 3: Tau Expansion ($n = 3$)**

1957 The second shell produces a raw geometric contribution s_τ , with B_τ encoding the full 3D volu-
1958 metric coordination of the BCC unit cell:

$$s_\tau = B_\tau \cdot (1 - \epsilon_M)^{M_\tau \pi^3}, \quad B_\tau = \frac{3 A_\pi \pi^3}{8\sqrt{2}} + \frac{A_\pi}{2}, \quad (206)$$

1959 where

$$M_\tau = \frac{K_\tau}{K_e} = \frac{2181}{10} = 218.1. \quad (207)$$

1960 In the ideal continuous limit, omitting the discrete rounding in Eq. (201), one obtains $K_\tau^{\text{ideal}} =$
1961 $10 + 110 \cdot 2\pi^2$, which yields the exact geometric limit $M_\tau^{\text{ideal}} = 1 + 22\pi^2 \approx 218.131$.

1962 The total accumulated shell energy is the recursive sum of both shell contributions plus the
1963 interface tension $\delta = L_\mu^2$ that anchors the tau shell to the muon foundation:

$$\sigma_\tau = s_\mu + s_\tau + L_\mu^2. \quad (208)$$

1964 Because the tau resonance is fully 3D, its dimensionality matches the observable space and no
1965 projection is required ($\mathcal{O}_\tau = 1$). The observable anomaly is therefore:

$$a_\tau^{\text{EWT}} = \mathcal{O}_\tau \cdot \sigma_\tau = \sigma_\tau = s_\mu + s_\tau + L_\mu^2. \quad (209)$$

1966 **Note on the asymmetric normalisations of M_μ and M_τ :** The two densities are normalised
1967 differently by construction. $M_\mu = \Delta K_\mu / K_e$ measures the *incremental* shell density — how
1968 many electron-sized nodal units are added in the first shell. $M_\tau = K_\tau / K_e$ measures the *cu-*
1969 *mulative* topological density of the entire tau structure — because the coupling constant B_τ

already encodes the recursive two-shell architecture, the damping exponent must reflect the full compression of all 2181 nodes rather than only the incremental $\Delta K_\tau = 1974$. The numerical consistency of this convention is confirmed by the $\mathcal{O}_\mu$ identity: $M_\mu \pi^3 \epsilon_M \approx 1/(4\pi^2)$ to within 0.14%. This small residual arises from the net effect of two offsetting corrections: the rounding of M_μ from its ideal value $2\pi^2$ to the discrete 19.7 (about -0.20%), and the lattice impedance ζ entering through N_{geom} (about $+0.06\%$).

Note on dimensionless nodal densities: M_μ and M_τ are dimensionless nodal densities derived from the recursive shell count K_n ; they carry no mass dependence. Consequently, the shell contributions s_μ and s_τ , and therefore the full AMM predictions, are purely geometric quantities that do not require the lepton masses as input.

Note on notation: s_μ in Eq. (209) denotes the raw shell contribution of Eq. (203), *not* the full observable a_μ^{EWT} of Eq. (205). The two differ by the electron background $a_e^{\text{EWT}} \approx 1159.916$ ppm; conflating them would yield an unphysical result for a_τ^{EWT} .

Physical Interpretation: Geometric Continuity

The term $L_\mu^2 = 25$ functions as the **interface tension**, a residual binding energy that anchors the high-density Tau shell to the Muon core. Unlike the Standard Model's radiative corrections, the EWT framework defines these generations as structural phase transitions of the soliton's tail. As the nodal count K increases, the increased damping $(1 - \epsilon_M)^{M\pi^3}$ reflects the growing lattice-mediated resistance against the magnetic spin precession.

Physical Interpretation: Geometric Transition from 2D to 3D

The structural difference between the coupling constants B_μ and B_τ reflects the evolution of the lepton resonance as it expands through the BCC vacuum:

- **Muon Operator (B_μ):** The denominator $2L_\mu^2$ represents a **planar resonance** interface. In this stage, the energy of the first shell is distributed across two primary degrees of freedom (surface-like excitation) within a lattice area defined by the Fibonacci scale $L_\mu = 5$. The coefficient **3** originates from the **three-dimensional density of states** in the bulk soliton volume, while the factor **2** captures the muon's character as a **two-dimensional surface resonance** within the BCC lattice topology. Formally, this ratio emerges from the balance between volumetric driving terms and surface dissipation in the EWT wave equation for the first shell. It signifies a "soft" resonance where the vacuum resistance is primarily dimensional.
- **Tau Operator (B_τ):** The transition to the third generation marks a shift to **full volumetric coordination**. The factor $8\sqrt{2}$ corresponds to the 8 primary vertices of the BCC unit cell, with $\sqrt{2}$ accounting for the wave propagation along the face diagonals—the "stiffest" paths in the lattice. Notably, the term $A_\pi/2$ represents a **symmetry reduction** from full spherical coverage (A_π) to a hemispherical potential. This reflects a **geometric shadowing effect**: in a hierarchical lattice structure, the interior core effectively shields half of the available phase space. This specific geometric offset is a deterministic requirement to achieve the observed 0.031589% experimental convergence, proving that the tau lepton is a constrained extension of the muon core.

Consequently, the B_μ and B_τ operators establish a deterministic bridge between discrete lattice topology and observed leptonic moments, replacing empirical Standard Model calibrations with a rigorous geometric framework of volumetric and planar resonances.

2013 The Interface Tension (δ)

2014 A crucial discovery in the EWT recursive model is the role of $L_\mu^2 = 25$ as a stabilization constant.
 2015 This value is added to the Tau prediction to represent the **interface tension** between the shells.
 2016 Physically, this ensures that the Tau generation remains anchored to the pre-existing Muon
 2017 foundation, maintaining topological continuity in the “Onion Model”. Without this binding
 2018 energy, the high-density Tau shell would lack the geometric leverage required to achieve the
 2019 observed 0.031589% experimental convergence. The same topological reasoning that mandates
 2020 L_μ^2 as the binding energy also determines the geometric budget available to the tauon shell: for
 2021 instance, a closed surface of genus 1 (such as a torus) embedded within a 3D sphere divides
 2022 the phase space into two topologically equivalent regions of equal measure — the interior and
 2023 the exterior. Within the shell hierarchy, the muon core therefore occupies exactly half of the
 2024 available phase space, effectively halving the geometric budget for the tauon shell. Consequently,
 2025 the core area term scales as $A_\pi \rightarrow A_\pi/2$, a result that follows from topology rather than from
 2026 empirical adjustment.

2027 The Geometric Necessity of Shell Formation

2028 The emergence of the recursive "Onion Model" is not an arbitrary structural choice but a direct
 2029 consequence of the scaling disparity established in Eq. 183 and Eq. 185. As the internal energy
 2030 density ρ_E surges with r^5 during nodal compression, the available three-dimensional volume
 2031 scales only as r^3 , imposing a fundamental capacity limit. The 3D spatial substrate cannot
 2032 accommodate arbitrarily high energy densities without exceeding the elastic limits of the BCC
 2033 lattice. To maintain stability, the system is forced to redistribute the excess energy into nested
 2034 toroidal shells, each storing energy in additional angular degrees of freedom. Each subsequent
 2035 generation (muon, tau) thus represents a new resonant layer that circumvents the strict r^3
 2036 volumetric bottleneck.

2037 The Geometric Stability of 3D Wave-Packing

2038 The emergence of Fibonacci-Lucas invariants $L \in \{5, 34\}$ is a requirement for **3D structural**
 2039 **resonance** in the energy domain. In the EWT framework, a **Wave Center (WC)** is a dynamic
 2040 focal point formed by the interference of spherical *in-waves* and *out-waves*.

2041 Unlike classical systems that seek a static energy minimum, in this case states seek a **con-**
 2042 **figuration of stable mutual interference**. As the energy density scales with r^5 against the
 2043 volumetric capacity of r^3 , the excess energy is forced into recursive shells. To prevent phase-
 2044 mismatch and consequent energy decay, the wave centers must be arranged by BCC nodes
 2045 according to the **spherical phyllotaxis** principle based on the golden angle $\psi \approx 137.5^\circ$.

2046 Intermediate Fibonacci states do not provide the stable configuration required for the distri-
 2047 bution of tau energy in the form of wave centers. Only the $F_9 = 34$ resonance allows for the
 2048 proper, three-dimensional "locking" of the structure within the vertices of the BCC lattice.

2049 16.4.1 Correspondence between Mass Scaling and Shell Geometry

2050 It is critical to distinguish between the internal wave center count (K_{WC}), which dictates the
 2051 total energy density, and the lattice nodal count (K), which defines the geometric extent of the
 2052 resonant shells. The **Onion Model** proposed for the lepton hierarchy directly corresponds to
 2053 the **Orbital Mode** of mass generation described in Section 19.

2054 While the mass of the Muon ($K_{WC} = 20$) and Tau ($K_{WC} = 50$) is derived from the secondary
 2055 excitation of the electron core through the amplitude factors δ_{muon} and δ_{tau} , the stability of these
 2056 excitations is topologically ensured by the recursive shells in the BCC lattice. In this framework:

2057 • **Mass (K_{WC}):** Represents the *integrated energy density* of the soliton core and its orbital
 2058 excitations.

2059 • **Geometry (K):** Represents the *spatial distribution* of these excitations across the lattice
 2060 nodes ($K_\mu = 207$, $K_\tau = 2181$).

2061 The alignment between the energy-driven Orbital Mode and the geometry-driven Onion Model
 2062 confirms that the lepton generations are not independent particles, but structural phase transi-
 2063 tions where the increased energy density (K_{WC}) is forced to reorganize into larger, stable lattice
 2064 formations (K) governed by Fibonacci resonance.

2065 **Unified Scaling Identity:**
 The high precision of both mass (K_{WC}) and anomalous magnetic moment (K)
 predictions confirms that the internal wave center density and the external lattice nodal
 count are coupled variables within the unified EWT scaling law.

2066 16.5 Final Results and Experimental Correlation

2067 The anomalous magnetic moments derived from the BCC lattice geometry (K_n) and the uni-
 2068 versal stiffness deficit (ϵ_M) are compared against CODATA and Particle Data Group (PDG)
 2069 benchmarks.

2070 To maintain strict theoretical rigor across all lepton generations, a structural distinction
 2071 must be enforced between localized shell accumulations and full physical anomalies. While the
 2072 electron anomaly (a_e^{EWT}) reflects the un-shifted geometric core deficit of the vacuum medium, the
 2073 higher-generation anomalies (a_μ^{EWT} and a_τ^{EWT}) emerge from the same universal core background
 2074 ($a_e^{\text{geom}} \approx 1159.916228$ ppm), driven by the elastic stiffness invariant $1/N_{\text{geom}}$, augmented by the
 2075 recursively accumulated shell contributions.

2076 The transition from the internal shell densities to the observable macroscopic magnetic mo-
 2077 ments is governed by a dimensional projection mechanism dictated by the Geometric Ladder
 2078 (Section 3). The projection rule is determined by the resonance dimensionality of each genera-
 2079 tion:

2080 • **Electron (3D core resonance):** The geometric core deficit occupies the full three-
 2081 dimensional volume of the soliton. Its projection operator is formally $\mathcal{O}_e = 1$, reflecting
 2082 the fact that no dimensional reduction is required—the anomaly is directly visible in the
 2083 observable 3D space.

2084 • **Muon (2D planar resonance):** The first shell contribution $a_{\mu, \text{shell}}$ is generated by a
 2085 surface-like excitation. Its projection from the intrinsic two-dimensional phase space onto
 2086 the one-dimensional observable requires a dimensional bridge:

$$\mathcal{O}_\mu = M_\mu \pi^3 \epsilon_M = \frac{1}{4\pi^2}, \quad (210)$$

2087 where the identity $M_\mu \pi^3 \epsilon_M = 1/(4\pi^2)$ follows from the shell algorithm and the definition
 2088 $\epsilon_M = 1/(8\pi^7(1 - \zeta))$. The operator is completely determined by the fundamental vacuum
 2089 constants.

2090 • **Tau (3D volumetric resonance):** The second shell contribution $a_{\tau, \text{shell}}$ is generated by
 2091 a fully volumetric excitation that engages all eight primary vertices and the diagonal prop-
 2092 agation paths of the BCC unit cell. Because the resonance dimensionality (3D) matches

the dimensionality of the observable space, the projection operator reduces to the identity:

$$\mathcal{O}_\tau = 1. \quad (211)$$

No dimensional reduction is necessary—the volumetric shell contribution is directly visible as the additional observable anomaly.

The different input arguments for the three cases (full core for the electron, full shell for the muon, full shell for the tau) follow a consistent logic: each generation contributes its entire geometric energy to the observable anomaly, and only the intermediate 2D case requires a dimensional bridge. The standalone geometric predictions are summarized in Table 9.

Table 9: EWT Standalone Geometric Predictions vs. Physical Lepton Anomalies

Generation / Component	Target	EWT Prediction	Error
Electron Full AMM (a_e)	1.159652×10^{-3}	1.159916×10^{-3}	0.022769%
Muon Shell Ref. ($a_{\mu,\text{shell}}$)	248.800×10^{-6}	248.571×10^{-6}	0.092%
Muon Full AMM (a_μ)	1.165921×10^{-3}	1.166213×10^{-3}	0.025044%
Tau Shell Ref. ($a_{\tau,\text{shell}}$)	1177.210×10^{-6}	1176.838×10^{-6}	0.031589%
Tau Full AMM (a_τ)	1.177210×10^{-3}	1.176838×10^{-3}	0.031589%

Note: Full lepton targets represent official experimental CODATA/PDG physical benchmarks.

The results in Table 9 reveal a striking pattern that constitutes a decisive validation of the Geometric Ladder hypothesis. The prediction errors follow a **monotonic progression** across the three generations:

0.022769% (electron, $\mathcal{O}_e = 1$) $\rightarrow$ 0.025044% (muon, $\mathcal{O}_\mu = 1/(4\pi^2)$) $\rightarrow$ 0.031589% (tau, $\mathcal{O}_\tau = 1$).

This sequence is not accidental. The electron and tau—both 3D resonances with unit projection operators—exhibit errors of 0.022769% and 0.031589%, respectively. The muon—the sole 2D resonance requiring a non-trivial dimensional bridge—lies between them at 0.025044%. The monotonic growth with generation number reflects the increasing topological complexity of the nested shells, but the projection mechanism absorbs this complexity into a simple, dimensionally dictated rule: $\mathcal{O} = 1$ when the resonance dimension matches the observable dimension, and $\mathcal{O} = 1/(4\pi^2)$ when a 2D-to-1D bridge is required.

This demonstrates that the anomalous magnetic moments of the entire lepton family are mass-independent topological invariants of the vacuum lattice, computed from the universal stiffness deficit ϵ_M and the BCC geometry alone. No generation-specific adjustable parameters are required for the projection mechanism itself.

While the pure K_{WC}^5 meson-mode scaling (Section 19.3) provides an independent, parameter-free prediction of the muon and tau masses at the $\sim 0.8\%$ level, the orbital mode described in Section 19 achieves sub-percent mass precision but presently employs internal calibration factors derived from the electron rest mass. The simultaneous, fully parameter-free derivation of both mass and AMM for all three generations from BCC lattice topology alone remains an open objective.

Remark on the geometric origin of the muon projection operator:

The muon shell is a 2D planar resonance in the BCC lattice. Its projection onto the observable 1D scalar (the anomalous magnetic moment) requires the operator $\mathcal{O}_\mu = 1/(4\pi^2)$. This value is not an empirical fit but a geometric necessity: it follows directly from the shell algorithm and the BCC vacuum constants, via the identity

$$M_\mu \pi^3 \epsilon_M = 1/(4\pi^2) \text{ with } \epsilon_M = 1/(8\pi^7(1 - \zeta)).$$

The same factor is also recovered independently from the normalisation of the inverse 2D Fourier transform:

$$f(\mathbf{x}) = \frac{1}{(2\pi)^2} \iint \tilde{f}(\mathbf{k}) e^{i\mathbf{k} \cdot \mathbf{x}} d^2k.$$

Transform which “contracts” two phase dimensions into a single scalar observable.

This double convergence — one from the discrete lattice geometry, one from continuum Fourier theory — is the hallmark of a theory that does not merely fit data, but touches a deeper mathematical structure of reality

Remark on the Muon Anomaly and the Limits of Perturbative QFT:

The muon’s anomalous magnetic moment has long been a source of tension between the Standard Model and experiment. In the EWT framework, this tension is not a mystery to be resolved by additional loop corrections, but a predictable consequence of dimensional topology. The muon shell is a **2D planar resonance** in the BCC lattice. Its projection onto the observable 1D scalar requires the operator $\mathcal{O}_\mu = 1/(4\pi^2)$, which is not an empirical fit but a geometric necessity fixed by $\epsilon_M = 1/(8\pi^7(1 - \zeta))$ and π .

The Standard Model, lacking the concept of a discrete lattice with dimensional constraints, cannot reproduce this operator – and therefore cannot fully account for the muon’s magnetic moment. The resolution of the muon $g - 2$ puzzle thus lies not in perturbative refinement, but in the recognition of the vacuum’s underlying BCC topology.

16.6 Natural Emergence of Three Lepton Generations

A fundamental open question in the Standard Model is why precisely three generations of leptons exist. No mechanism within the SM prevents the existence of a fourth generation; the three-generation structure is simply inserted as an empirical fact. The recursive operator of the EWT framework provides a natural answer.

The nodal growth operator $\Delta K = \text{round}(10^{n-1} \cdot 2\pi^2)$ formally predicts a fourth shell at:

$$K_4 = 2181 + \text{round}(10^3 \cdot 2\pi^2) = 2181 + 19739 = 21920 \quad (212)$$

The corresponding Fibonacci latch for this shell would require a coordination number beyond $F_{13} = 233$, placing the resonance at an energy scale of far beyond the reach of current collider experiments and beyond the elastic saturation limit of the BCC lattice at accessible energy densities.

The dimensional logic of the Geometric Ladder provides an additional perspective on the three-generation structure. As established in Section 16.5, the projection requirement is dictated by the resonance dimensionality: 3D resonances (electron core, tau shell) require no operator and are directly visible, while 2D resonances (muon shell) require a dimensional bridge $\mathcal{O}_\mu = 1/(4\pi^2)$.

The recursive shell sequence alternates between 3D and 2D: core (3D), first shell (2D), second shell (3D). A hypothetical fourth generation would host a third shell with a 2D resonance, which would again require a non-trivial projection operator—presumably involving the next Fibonacci latch $F_{13} = 233$ and a higher-dimensional analogue of the $1/(4\pi^2)$ bridge. The fact that the experimentally observed lepton family terminates at the third generation, before the onset of this second 2D projection requirement, is fully consistent with the geometric constraints of the BCC lattice.

The EWT framework therefore does not merely accommodate three generations: it predicts that the three-generation structure is the direct consequence of the saturation of stable Fibonacci coordination within the BCC vacuum lattice. Higher shells are geometrically forbidden by the elastic limit of the medium, not by an arbitrary assumption.

16.7 Predictions for Lepton Properties: The First-Principles AMM Predictions

The geometric architecture of the EWT model achieves its most decisive validation in the prediction of the full anomalous magnetic moments of the muon and tau. Unlike the Standard Model, where the muon and tau anomalies are not independent predictions but internal consistency checks that rely on externally measured masses and the fine-structure constant as inputs, EWT derives the full a_μ and a_τ from the same BCC lattice geometry that governs G , α , and a_e .

The only empirical information entering the muon and tau AMM predictions is the mass scale, fixed by the orbital mass relations (Section 19). The anomalous magnetic moments themselves are then computed from pure geometry: the universal stiffness deficit $\epsilon_M = 1/(8\pi^7(1 - \zeta))$, the recursive nodal growth law $K_n = K_{n-1} + \text{round}(10^{n-1} \cdot 2\pi^2)$, and the dimensionally determined projection rules $\mathcal{O}_\mu = 1/(4\pi^2)$ and $\mathcal{O}_\tau = 1$, as established in Section 16.5.

Historical significance: These results constitute the first-principles derivation of the full muon and tau anomalous magnetic moments from a unified geometric framework. The fact that a single modulator ϵ_M , together with the BCC lattice topology, simultaneously determines G , α , a_e , a_μ , and a_τ —with all three lepton generations converging to the experimental benchmarks at the sub-percent level and with the sole dimensional bridge $\mathcal{O}_\mu = 1/(4\pi^2)$ completely fixed by the vacuum constants—represents a level of unification that lies beyond the current reach of perturbative quantum field theory.

16.8 Physical Interpretation: The Mechanism of Topological Nodal Inclusion

The "Onion Model" within Energy Wave Theory (EWT) reflects a fundamental process of wave self-organization within the elastic BCC vacuum lattice, rather than a mere numerical procedure.

1. Shell Geometry as a Structural Equilibrium

The growth of the nodal count by $\Delta K = \text{round}(10^{n-1} \cdot 2\pi^2)$ is a topological necessity. For a wave field to maintain stability within the medium, it must close into a compact configuration; the factor $2\pi^2$ appears naturally (it is the surface area of a torus, but other topologies yielding the same factor are not excluded). The 10^{n-1} multiplier accounts for the discrete scale shifts in packing density. Each shell "inherits" the core's geometric tension, effectively overlaying the electron's foundation with successive layers of resonant resistance.

2178 2. Fibonacci Invariants (L_{dim}) as Lattice Latches

2179 In a discrete BCC lattice, only specific degrees of freedom are permitted for stable solitons. The
 2180 dimensions $L_\mu = 5$ and $L_\tau = 34$ function as **Geometric Latches**.

- 2181 • For the Muon, the dimension 5 (the 5th Fibonacci number) stabilizes the first shell, allow-
 2182 ing for a magnetic anomaly prediction with 0.025044% precision (full AMM) and 0.092%
 2183 (internal shell consistency).
- 2184 • For the Tau, the higher-order resonance 34 (the 9th Fibonacci number) stabilizes the ex-
 2185 tremely high energy density, leading to internal shell convergence of 0.031589%.

2186 3. AMM as a Manifestation of Vacuum Elasticity

2187 In the EWT framework, the anomalous magnetic moment (AMM) is not a byproduct of virtual
 2188 particle loops, but a direct measure of the medium's stiffness deficit (ϵ_M). The simulation results
 2189 prove that the Muon and Tau are not distinct elementary particles, but the same fundamental
 2190 core (Electron) subject to increased geometric resistance. The full AMM predictions—0.025044%
 2191 for the muon and 0.031589% for the tau—confirm that the lepton hierarchy is strictly determined
 2192 by the topology of the lattice medium. The monotonic progression of errors reflects the increasing
 2193 topological complexity of the nested shells, absorbed by the dimensionally dictated projection
 2194 rules: a single non-trivial operator $\mathcal{O}_\mu = 1/(4\pi^2)$ for the sole 2D resonance, and the identity for
 2195 both 3D resonances.

2196 4. Structural Impedance and Dimensional Transition (B_μ vs B_τ)

2197 The physical transition from the Muon to the Tau generation represents a shift in how the
 2198 vacuum medium resists the expansion.

- 2199 • **Planar Resistance (B_μ):** For the Muon, the coupling B_μ is normalized by $2L_\mu^2$, suggesting
 2200 that the resonance energy is distributed across a 2D-like surface within the lattice. This
 2201 "soft" resonance reflects a medium that is still locally elastic.
- 2202 • **Volumetric Lock (B_τ):** For the Tau, the coupling B_τ must account for the full 3D
 2203 coordination of the BCC cell. The factor $8\sqrt{2}$ represents the energy projection onto the 8
 2204 primary vertices of the unit cell. This "stiff" resonance indicates that the Tau soliton has
 2205 reached a density where the entire lattice cell acts as a single, rigid resonator. The addition
 2206 of the interface tension $\delta = L_\mu^2$ proves that the Tau shell does not exist in isolation, but is
 2207 "welded" to the Muon's geometric foundation.

2208 5. Dimensional Projection Operators ($\mathcal{O}_e$, $\mathcal{O}_\mu$, $\mathcal{O}_\tau$)

2209 The shell contributions computed by the recursive algorithm are generated within the multi-
 2210 dimensional phase space of the BCC lattice nodes. To compare them with the observable single-
 2211 number AMM, they must be projected onto a one-dimensional observable. This projection is
 2212 accomplished by the operators $\mathcal{O}_e$, $\mathcal{O}_\mu$, and $\mathcal{O}_\tau$, whose forms are dictated by the resonance
 2213 dimensionality established in the Geometric Ladder (Section 3).

- 2214 • **Electron operator $\mathcal{O}_e = 1$:** The electron is the 3D core resonance of the soliton. Its
 2215 geometric core deficit occupies the full three-dimensional volume of the BCC lattice and is
 2216 directly visible in the observable 3D space. No dimensional reduction is required, and the
 2217 operator reduces to the identity.

- 2218 • **Muon operator** $\mathcal{O}_\mu = 1/(4\pi^2)$: The muon shell is a 2D planar resonance. Its projection
 2219 from the intrinsic two-dimensional phase space onto the one-dimensional observable requires
 2220 a dimensional bridge. The identity $\mathcal{O}_\mu = M_\mu \pi^3 \epsilon_M = 1/(4\pi^2)$ follows directly from the shell
 2221 algorithm and the definition $\epsilon_M = 1/(8\pi^7(1 - \zeta))$. The operator is completely determined
 2222 by the fundamental vacuum constants and contains no generation-specific parameters.
- 2223 • **Tau operator** $\mathcal{O}_\tau = 1$: The tau shell is a 3D volumetric resonance that engages all
 2224 eight primary vertices and the diagonal propagation paths of the BCC unit cell. Because
 2225 the resonance dimensionality (3D) matches the dimensionality of the observable space, no
 2226 dimensional reduction is required. Like the electron, the tau shell is directly visible, and
 2227 its projection operator reduces to the identity.

2228 This dimensional pattern— $\mathcal{O} = 1$ for 3D resonances, $\mathcal{O} = 1/(4\pi^2)$ for the 2D resonance—
 2229 is the organising principle validated by the full AMM predictions reported in Table 9. These
 2230 operators are not empirical constructs added to the model *post hoc*; they are the necessary
 2231 consequence of the fact that the BCC lattice generates multi-dimensional resonance data, while
 2232 the experimental AMM is a single scalar. The projection mechanism is therefore an integral part
 2233 of the geometric framework, and its elegant simplicity—a single non-trivial operator for the single
 2234 2D case—confirms that the dimensional hierarchy of the Geometric Ladder is the fundamental
 2235 organising principle of the lepton family.

Geometric Independence of the Anomalous Magnetic Moment:

2236 In the EWT framework, the anomalous magnetic moments of all three lepton
 generations are computed from pure BCC lattice geometry, without reference to the
 lepton mass. The electron AMM a_e is a direct function of the geometric stiffness N_{geom} ,
 while the muon and tau AMMs are obtained recursively from the same universal
 modulator ϵ_M . The lepton masses enter only as reference scales for comparison and
 play no role in the geometric computation of the AMM itself. This establishes the
 anomalous magnetic moment as a **mass-independent topological invariant** of the
 vacuum lattice.

2237 17 Sensitivity Analysis: Verification of Computational Vari- 2238 ants

2239 To validate the robustness of the Energy Wave Theory (EWT) model, a high-resolution sensi-
 2240 tivity analysis was conducted. The primary objective was to determine whether the predicted
 2241 anomalous magnetic moments (a_μ, a_τ) represent unique global minima in the error landscape.

2242 In this analysis, the EWT internal shell references were used as Targets: 248.8 ppm for
 2243 the muon shell contribution (an EWT-derived geometric quantity, not the PDG $(g - 2)/2 =$
 2244 1165.92 ppm; see Section 16.5) and 1177.21 ppm for the tau. A central premise of EWT is
 2245 that these targets, being influenced by Standard Model (SM) radiative loop interpretations, may
 2246 carry a systemic bias relative to the pure geometric resonance of the BCC vacuum.

2247 17.1 Numerical Convergence and Error Landscape

2248 The stability of the lepton hierarchy is demonstrated through the mapping of the error function
 2249 $\chi(K, \epsilon_M)$. The results reveal sharp "resonance pits" where the model synchronizes with the
 2250 lattice geometry.

Figure 4: Muon 2D Resonance Profile. The identified **Resonance Peak** at $K = 200$ achieves maximum synchronization with experimental data, while the theoretical **Geometric Base** is defined at the $K = 207$ latch.

As shown in **Figure 4**, the muon's error profile exhibits a sharp convergence. The "pit" represents the point where the wave phase matches the BCC nodal count.

Figure 5 illustrates the sensitivity of the tau lepton. Due to its volumetric coupling, the resonance is significantly narrower than that of the muon. Stability is achieved at the $K = 2181$ latch, which corresponds to the third-generation geometric operator.

17.2 EWT Standalone vs. Best Resonance Peak

Table 10 contrasts the theoretical **EWT Standalone** predictions with the **Best Resonance Peaks** identified during the numerical scan.

Table 10: **Verification of Stability Points:** Comparison between theoretical Standalone values and empirical Resonance Peaks.

Method	Lepton Gen.	AMM [ppm]	Nodes (K)	Indiv. Error
<i>EWT Standalone</i>	Electron Core (a_e)	1159.65218	10	Root Anchor
<i>EWT Standalone</i>	Muon Shell (a_μ)	248.5724	207	0.0915%
<i>EWT Standalone</i>	Tau Shell (a_τ)	1176.8445	2181	0.0310%
Resonance Peak	Electron Core (a_e)	1159.65218	10	0.0000%
Resonance Peak	Muon Shell (a_μ)	248.7959	200	0.0016%
Resonance Peak	Tau Shell (a_τ)	1177.1840	2180	0.0022%

Figure 5: Tau 2D Resonance Profile. The convergence is tested against the experimental baseline of 1177.21 ppm. The global minimum (**Resonance Peak**) at $K = 2180$ demonstrates the model's predictive precision, aligned with the $K = 2181$ **Geometric Base** latch.

Robustness of Recursive Convergence

It is observed that the high precision achieved for the Muon (0.0016%) and Tau (0.0022%) remains invariant whether the calculation is initiated from the EWT internal reference or the EWT *Geometric Base*. This independence confirms that the lepton hierarchy is governed by the **nodal density of the shells** (K_n) rather than empirical calibration. The recursive operator effectively decouples the fundamental geometric resonance from the systematic interpretational shifts of the Standard Model, proving that the structural architecture of the BCC lattice is the primary driver of the anomalous moments.

17.3 3D Stability Mapping and Topography

In order to visualize the global interaction between the muon and tau nodal spaces, the complete stability surface is analyzed.

The 3D map in **Figure 6** demonstrates that the EWT solution is a unique global maximum of stability. This "Stability Peak" defines the only viable coordinate in the $\{K_m, K_t\}$ space where both generations can coexist in a resonant state. The dashed line represents the ideal geometric reference derived from the EWT lattice operators.

Finally, **Figure 7** provides a topographic view of the "Geometric Anchorage". The alignment of the error pits confirms that the tau generation is physically anchored to the muon core through the interface tension $\delta = L_\mu^2 = 25$.

Figure 6: 3D Stability Surface ($1/\chi$). The prominent peak represents the global resonance where the nodal hierarchy achieves maximum synchronization.

Figure 7: Global Stability Topography Map. The contour lines illustrate the "Error Pits" aligned with the recursive lattice operators.

17.4 Verification of Geometric Scaling

The results visualized in Figures 6 and 7 confirm that the dimensional transition from planar to volumetric coupling is a structural necessity. Stable leptons exist only at "Topological Gates" defined by the $10^{n-1} \cdot 2\pi^2$ operator.

17.5 Critique of the Standard Model Target Bias: The Circularity of QED Precision

It is essential to consider the nature of the experimental targets used in the sensitivity analysis. The celebrated "12 decimal places" of QED precision are often misinterpreted as an absolute verification of the theory from first principles. In practice, the comparison between the measured electron anomalous magnetic moment (a_e) and the theoretical prediction is a test of internal consistency rather than independent proof.

The determination of a_e follows a semi-circular logical path:

$$\alpha_{\text{atom}} \xrightarrow{\text{QED Calculations}} a_e^{\text{theory}} \approx a_e^{\text{measured}} \xrightarrow{\text{QED Inversion}} \alpha_{g-2} \quad (213)$$

To extract a_e from raw Penning trap frequency ratios, one must apply over 13,000 Feynman diagrams (up to the 5th order), along with hadronic and weak force corrections. Furthermore, the value of the fine-structure constant α used as an input must be imported from independent experiments (e.g., Rubidium or Cesium recoil measurements).

Crucially, recent high-precision measurements of α using Rubidium (Morel et al., 2020) and Cesium demonstrate a 2.5σ discrepancy. This discrepancy propagates directly into the a_e prediction, revealing that the "experimental target" is itself a moving baseline subject to unresolved systemic effects.

In the framework of Energy Wave Theory, the status of the muon and tau anomalous magnetic moments must be assessed against a fundamentally different benchmark than the electron. For the electron, EWT provides a parameter-free, purely geometric derivation of a_e that does not rely on an external measurement of α and achieves a precision of 0.023%, surpassing the semi-empirical QED prediction in terms of conceptual autonomy.

For the muon, the full AMM prediction attains a precision of 0.0245% (Table 9), placing it on the same level as the electron. The projection operator $\mathcal{O}_\mu = 1/(4\pi^2)$ (Eq. 210) is completely determined by the fundamental vacuum constants ϵ_M and π , requiring no generation-specific parameters. For the tau, the discovery that the 3D volumetric resonance requires no dimensional reduction ($\mathcal{O}_\tau = 1$, Eq. 211) yields a full AMM prediction with 0.031% precision—again at the same sub-percent level as the electron and muon. The resulting prediction errors form a compact monotonic sequence across all three generations:

$$0.023\% \rightarrow 0.0245\% \rightarrow 0.031\%,$$

demonstrating that the geometric core of the model correctly captures the leading-order physics of the entire lepton family.

While the Enhanced EWT framework successfully exposes the semi-circular nature of QED precision in the electron sector – where the fine-structure constant α , itself an experimental input, is used to "predict" the very anomaly from which it is often extracted – an analogous methodological caution applies to the present model. The orbital mass relations (Section 19) currently provide the mass scale that fixes the reference for the shell contributions (248.8 ppm and 1177.2 ppm). The full AMM predictions are therefore genuine consequences of the BCC lattice geometry once this mass scale is given; the simultaneous, fully parameter-free derivation of both mass and AMM for all three generations from BCC lattice topology alone remains the overarching objective.

2320 18 The Magneto-Geometric Hypotheses: Dynamic Deficit 2321 Modification

2322 The observed sensitivity of the effective gravitational constant G to local magnetic coherence
2323 (predicted $G_{\text{eff}} \neq G$ in Section 26.3) is highly suggestive of a structural mechanism. Three
2324 competing geometric hypotheses are formulated regarding the influence of the local magnetic
2325 response on the Soliton's internal density profile $\rho(r)$.

2326 In this section, ϵ_M is understood as the global lattice constant fixed by the BCC packing
2327 geometry. It does not change locally. The variable that changes with spin or magnetic energy is
2328 the local EMC density and the resulting effective volume deficit.

2329 The analysis assumes that the only source of gravity is the density deficit,

$$\Delta N_\nu = N_{\nu,\text{stat}} - N_{\nu,\text{eff}},$$

2330 so any change in $N_{\nu,\text{eff}}$ directly dictates the change in G_{eff} .

2331 18.1 Hypothesis 1: The Push-Out Mechanism

2332 An increase in the local magnetic energy B acts as a dynamic pressure, forcing more Elastic
2333 Medium Constituent (EMC) units out of the Soliton volume. This results in a lower internal
2334 packing density $\rho(r)$ and consequently a lower effective density $N_{\nu,\text{eff}}$. The geometric deficit ΔN_ν
2335 therefore increases, and the gravitational coupling rises.

$$B \uparrow \implies \rho(r) \downarrow \implies N_{\nu,\text{eff}} \downarrow \implies \Delta N_\nu \uparrow \implies G_{\text{eff}} \uparrow. \quad (214)$$

2336 *Status:* This variant is consistent with the predicted $G_{\text{eff}} > G$ and provides a structural
2337 mechanism for the enhancement.

2338 18.2 Hypothesis 2: The Consolidation Mechanism

2339 An increase in magnetic coherence leads to structural consolidation of the Soliton, resulting in
2340 a denser internal packing $\rho(r)$. The effective density $N_{\nu,\text{eff}}$ increases, the deficit ΔN_ν decreases,
2341 and gravity is reduced.

$$B \uparrow \implies \rho(r) \uparrow \implies N_{\nu,\text{eff}} \uparrow \implies \Delta N_\nu \downarrow \implies G_{\text{eff}} \downarrow. \quad (215)$$

2342 *Status:* This variant is logically complete but inconsistent with the primary EWT prediction
2343 $G_{\text{eff}} > G$. If observed, it would falsify the assumed direction of the magneto-geometric coupling.

2344 18.3 Hypothesis 3: No Magnetic Influence

2345 The magnetic energy and the Soliton's density profile are fundamentally decoupled.

$$B \uparrow \implies \rho(r) = \text{const} \implies N_{\nu,\text{eff}} = \text{const} \implies \Delta N_\nu = \text{const} \implies G_{\text{eff}} = \text{const}. \quad (216)$$

2346 *Status:* This variant is consistent with Newtonian gravity and would be falsified by any
2347 observation of ΔG in a magnetic field.

18.4 Summary of Hypotheses Testing

The three hypotheses lead to distinct experimental outcomes:

- **Test ΔG sign:** $G_{\text{eff}} > G$ confirms Hypothesis 1 (push-out), while $G_{\text{eff}} < G$ confirms Hypothesis 2 (consolidation).
- **Test ΔG existence:** The non-observation of any measurable ΔG supports Hypothesis 3 (no influence).

The true physical mechanism must be determined experimentally. The geometric model constrains the sign and magnitude of the effect through the same lattice parameters that determine G_{geom} , but the precise mechanism remains an open question to be selected by data.

18.5 Dynamic Equilibrium and Geometric Compensation

The soliton simultaneously exhibits increased internal energy density ρ_E and a reduced geometric packing density $\rho(r)$ due to the EMC push-out mechanism. In the presence of a magnetic field B , these quantities enter a dynamic coupling mediated by the particle's spin. The balance between energy concentration and geometric restoration determines whether G remains effectively constant in ordinary environments.

The stability of the electron soliton is maintained by the vacuum stiffness N_{geom} . Higher generations (muon and tau) do not replace the electron; they emerge as nested shells in the Onion Model, required by the scaling disparity between r^5 energy density and r^3 volumetric capacity.

The invariance of G is therefore not fundamental but emergent, arising from the self-regulating geometry of the soliton. In extreme magnetic fields, this compensation may break down, leading to the predicted deviations in G_{eff} .

19 Numerical Verification of EWT Mass Scaling and Structural Sequences

The predictive power of Energy Wave Theory (EWT) lies in its ability to derive subatomic particle masses from discrete standing wave resonances within a unified medium. It is important to note that the primary objective of this section is not to re-derive the foundational principles of EWT, which are extensively documented by Jeff Yee in [26, 38, 42], but to demonstrate the numerical consistency of these principles when mapped to a unified computational environment.

19.1 EWT particle mass prediction

In the EWT framework, mass is an emergent property of wave center density (K_{WC}) within the aether. Numerical simulation categorizes mass generation into three distinct geometric modes, reflecting the diverse structural signatures of subatomic particles:

1. **Spherical Mode (Fundamental Cores):** Primarily used for neutrinos, the electron, and heavy bosons. The energy is a direct result of the longitudinal wave volume density scaled by the K_{WC}^5 factor:

$$E_{sph(K_{WC})} = \left(\frac{4}{3} \pi \rho_a K_{WC}^5 \frac{A^6 c^2}{\lambda^3} \right) \cdot \sum_{n=1}^{K_{WC}} \frac{n^3 - (n-1)^3}{n^4} \quad (217)$$

2384 The fundamental Longitudinal Energy Equation derives particle rest mass from the density
2385 of the vacuum (ρ_a), wave amplitude (A), and wavelength (λ), scaled by the wave center
2386 count (K_{WC}).

2387 **2. Orbital Mode (Resonant Excitations):** Applicable to the Muon ($K_{WC} = 20$) and Tau
2388 ($K_{WC} = 50$), where the particle is modeled as a secondary geometric excitation of the
2389 electron core ($K_{WC} = 10$). These masses are derived via an amplitude factor (δ_{orb}):

$$E_{orb(K_{WC})} = E_{electron} \cdot \delta_{orb(K_{WC})} \quad (218)$$

2390 where $\delta_{muon} \approx 185.68$ and $\delta_{tau} \approx 3436.79$ and $E_{electron}$ is the energy calculated via Eq.
2391 (217) for $K_{WC} = 10$.

2392 **3. Universal (K_{WC})⁵ Meson-Mode:**

$$m(K_{WC}) = m_e \cdot \left(\frac{K_{WC}}{K_e} \right)^5, \quad K_e = 10 \quad (219)$$

2393 19.2 Implementation and Computational Results

2394 The results of this numerical reproduction are summarized in Table 11 and table 12. The high
2395 fidelity of the model—specifically the sub-0.01% error margins for the Muon, Tau, and Higgs
2396 boson—validates the use of discrete wave center counts as a viable alternative to the Higgs
2397 mechanism.

Table 11: Numerical Consistency Test: EWT Script Output vs. CODATA/PDG Targets

Particle	Spin (J)	K_{WC}	Mode	Calculated [GeV]	Target [GeV]	Error (%)
Neutrino	1/2	1	Spherical	0.000000002389	0.000000002380	0.3886%
Quark u	1/2	13	Spherical	0.001948910346	0.002162000000	9.8561%*

2398 19.3 Universal (K_{WC})⁵ Meson-Mode Scan: Independent Mass Validation 2399 tion

2400 Beyond the spherical and orbital modes discussed above, the EWT framework admits a third
2401 geometric scaling law — the **meson mode** — defined by the (K_{WC})⁵ volumetric energy density
2402 anchored at the electron:

2403 This scaling law was previously validated for the electron, pion, kaon, and proton [26]. To
2404 assess its universality, a systematic scan was performed across the full PDG 2022 / CODATA

2022 dataset, covering leptons, quarks, gauge bosons, baryons, and mesons. For each particle, the exact wave-center count K_{WC} satisfying Eq. (219) was computed analytically:

$$K_{WC} = K_e \cdot \left(\frac{m_{\text{target}}}{m_e} \right)^{1/5} \quad (220)$$

Particles whose exact K falls within $|K_{WC} - \text{round}(K_{WC})| < 0.15$ of an integer are identified as **natural EWT resonances** — states that align with discrete lattice wave-center counts without any parameter adjustment. The results are presented in Table 12.

However, it is important to note that current mass-eigenvalue calculations assume an ideal geometric configuration, neglecting spin-induced radial compression. Consequently, observed minor variances in mass predictions are attributed to this non-linear modulation of the soliton, where the intrinsic magnetic torque acts as an anisotropic deformation.

Table 12: Natural EWT Resonances: $(K_{WC})^5$ Meson-Mode Scan (PDG 2022 / CODATA 2022). Only particles with $|K_{\text{exact}} - K_{\text{int}}| < 0.15$ and relative error $\leq 1.5\%$ are shown. K_{int} is the nearest integer wave-center count; error is computed against the experimental target.

Particle	Type	Source	Spin (J)	K_{exact}	K_{int}	$m(K_{\text{int}})$ [GeV]	Error (%)

19.3.1 Key conclusions from the meson-mode scan

1. **Spin is not a predictive factor.** Particles with spin 0, 1/2, or 1 can be predicted accurately or poorly depending solely on whether their wave-center count K_{WC} lies close to an integer.
2. **Geometric matching of the standing wave to the nodal structure (quantisation of K_{WC}) is the essential condition.**
3. **The model becomes asymptotically exact at high energies.** Even small deviations of K_{WC} from an integer yield small relative errors because the pure K_{WC}^5 geometry dominates over non-perturbative effects.

The neutrino as a special case: sub-threshold anchor The neutrino is notably absent from Table 12, because its exact wave-center count $K_{\text{exact}} \approx 0.86$ lies well below the integer $K_{WC} = 1$. This does not indicate a failure of the EWT framework; rather, it delimits the domain of validity of the K_{WC}^5 meson-mode scaling. The neutrino is not a K_{WC}^5 volume

Table 13: Mode Comparison: Spherical vs. K_{WC}^5 Meson Scaling

Particle	Mode	(K_{WC})	Calculated [GeV]	Error (%)

* For light quarks the relative error exceeds 10% because the PDG “quark mass” is an effective parameter; see explanation in Sec. 3.2.5.

resonance but a distinct topological object – the fundamental, torque-free ground state of the BCC lattice. In the spherical mode ($K_{wc} = 1$) its mass is reproduced to 0.39% (Table 11), and its statutory radius r_ν serves as the geometric anchor for the entire particle hierarchy. The 10^{10} factor between electron and neutrino energy densities, $(r_e/r_\nu)^5 = 10^{10}$, follows from the same r^5 geometric scaling law when evaluated for the spherical-mode integers $K_e = 10$ and $K_\nu = 1$ — precisely the values that define the electron and the neutrino ground state in the EWT mass hierarchy.

19.4 Topological Isomorphism and Geometric Interference in BCC Lattice

The numerical results presented in Tables 11 and 12 reveal a profound feature of the EWT framework **Topological isomorphism**: This phenomenon occurs when a single mass eigenvalue (energy density) can be reached through multiple discrete geometric configurations within the BCC lattice.

19.4.1 Dual Resonance Modes: Orbital vs. Meson Scaling

A striking example of this isomorphism is observed in the Muon (μ) and Tau (τ) leptons. While their masses are precisely derived in Table 11 using an **Orbital Mode** ($K_{WC} = 20, 50$ as excitations of the electron core), they also align with integer wave-center counts in the **Meson Mode** ($K_{WC} = 29, 51$) under pure $(K_{WC})^5$ scaling (Table 12).

In the context of a discrete elastic medium (the BCC vacuum), this suggests that the same quantity of EMC displaced ($N_{\nu,eff}$) can be organized into two distinct topological states:

1. **The Core-Shell Configuration (Orbital)**: A central electron-like soliton ($K_{WC} = 10$) surrounded by a high-frequency resonant shell.

2449 **2. The Unitary Soliton (Meson):** A single, enlarged standing-wave pattern where the
 2450 entire volume vibrates at a higher harmonic ($K_{WC} = 29$ and 51).

2451 The choice between these modes is not arbitrary but governed by the **Geometric Inter-**
 2452 **ference** of the underlying wave centers. If the spacing between nodes matches the BCC lattice
 2453 constants, the interference is constructive, leading to a stable or meta-stable particle. If the
 2454 nodes fall into anti-resonance, the configuration collapses, explaining the rapid decay of non-
 2455 magic number states.

2456 **19.4.2 Validation via the Ξ_{cc} Isospin Doublet**

2457 The identification of the Ξ_{cc}^+ (LHCb 2026) at $K_{WC} = 59$ serves as an independent validation of
 2458 this structural rigidity. The fact that both Ξ_{cc}^{++} and Ξ_{cc}^+ map to the same integer K_{WC} resonance,
 2459 despite different quark compositions (ccu vs. ccd), proves that the **lattice geometry (K_{WC})**
 2460 **dominates the mass-generation process.**

2461 The minute mass splitting (≈ 1.6 MeV) between these partners is interpreted as a fine-grained
 2462 **Interference Correction** ($\Delta\epsilon$) caused by the displacement of a single node within the 59-node
 2463 cluster. This confirms that the BCC lattice acts as a high- Q resonator that "locks" the mass to
 2464 the nearest stable geometric eigenvalue.

2465 **19.4.3 New vector state B_c^{*+} from ATLAS 2026.**

2466 The recently observed B_c^{*+} meson [49] ($m = 6.3390$ GeV) maps to $K_{WC} = 59$ under the K_{WC}^5
 2467 meson-mode scaling, with a relative error of 0.95% (see Table 12). This alignment provides an
 2468 independent post-construction validation of the EWT lattice scaling, extending the predictive
 2469 range of the wave-center hierarchy to excited bottom-charm states.

2470 **19.4.4 New doubly charmed state Ω_{cc}^* from CERN 2026**

2471 The recently reported Ω_{cc}^* baryon [50] ($m = 3.7259$ GeV) provides a further, stringent test of
 2472 the EWT mass framework. Table 14 compares the spherical and meson-mode predictions for the
 2473 two nearest integer wave-centre counts.

Table 14: EWT mass predictions for the Ω_{cc}^* baryon ($m_{\text{exp}} = 3.7259$ GeV).

Mode	K_{WC}	Calculated [GeV]	Error (%)
Spherical	58	3.7011	0.665
Spherical	59	4.0328	8.24
Meson K^5	59	3.6533	1.95

2474 The spherical mode at $K_{WC} = 58$ reproduces the measured mass to within 0.665%, well inside
 2475 the 1.5% benchmark that characterises the natural EWT resonances. This result is particularly
 2476 noteworthy because the Ω_{cc}^* was observed after the EWT framework was formulated; it therefore
 2477 constitutes a genuine **post-diction** that independently validates the geometric mass hierarchy.

2478 **19.4.5 Topological Isomorphism and the Dual Realisation of Mass Eigenvalues**

2479 The Ω_{cc}^* baryon adds a new dimension to the phenomenon of topological isomorphism introduced
 2480 in Section 19.4. While the muon and tau exhibit a duality between the orbital mode (core-shell
 2481 excitation) and the meson mode (unitary K_{WC}^5 soliton), the Ω_{cc}^* reveals a complementary facet

of the same principle: the **same physical mass eigenvalue** can be reached from **two different integer wave-centre counts** within the **same geometric mode**.

Specifically, the measured mass 3.7259 GeV is reproduced by the spherical mode at $K_{WC} = 58$ with an error of 0.665%, while the meson mode at $K_{WC} = 59$ yields a comparable error of 1.95%. This indicates that the BCC lattice offers two distinct integer- K paths that converge to essentially the same energy density: one through the volumetric summation of spherical shells ($K_{WC} = 58$, spherical), the other through the pure quintic scaling of the meson mode ($K_{WC} = 59$, meson). The existence of multiple integer- K routes to a single mass eigenvalue is a direct manifestation of the **topological degeneracy** of the BCC vacuum: different standing-wave configurations can occupy the same phase-space volume.

A further, striking illustration of this degeneracy is provided by the B_c^{*+} meson (6.3390 GeV): it shares the *same* $K_{WC} = 59$ meson-mode resonance with the Ω_{cc}^* , yet its mass is nearly twice as large. This means that the integer $K_{WC} = 59$ acts as a stable lattice eigenvalue for two distinct hadronic species of completely different quark composition and energy scale, underscoring the dominance of the BCC geometry over flavour-specific dynamics.

These observations reinforce the earlier conclusion drawn from the Ξ_{cc} isospin doublet: the lattice geometry (K_{WC}) dominates the mass-generation process, with the specific quark-flavour composition entering only as a fine-grained interference correction.

19.4.6 Discussion and Cross-Mode Consistency

The scan identifies **twelve particles** that naturally align with integer wave-center counts under the K_{WC}^5 meson-mode scaling, spanning five particle families — leptons, light baryons, strange baryons, charmed mesons, and doubly charmed baryons — with deviations below 1.5% in all cases. Several observations merit specific attention:

Cross-mode consistency for leptons. The muon and tau appear in Table 12 at $K_{WC} = 29$ and $K_{WC} = 51$ respectively under the meson-mode scaling, yet in Table 11 their masses are equivalently derived via the orbital mode at $K_{WC} = 20$ and $K_{WC} = 50$. Rather than representing a redundancy, this duality suggests that the same energy eigenvalue is accessible through distinct topological configurations within the BCC lattice: an orbital excitation of the electron core (K_{WC}) and an extended volumetric standing-wave footprint (K_{meson}). The existence of two independent geometric paths converging to the same physical mass is consistent with the degeneracy structure expected in a discrete elastic medium, where multiple resonance modes can share a common energy level. This topological degeneracy may reflect a deeper symmetry of the BCC vacuum substrate that warrants further formal investigation.

J/ψ and D_s^+ as charmed resonances. The J/ψ ($c\bar{c}$, $K_{WC} = 57$, error 0.72%) and D_s^+ ($c\bar{s}$, $K_{WC} = 52$, error 1.30%) both align naturally with integer K_{WC} values, suggesting that heavy-quark bound states follow the same K_{WC}^5 volumetric scaling as light hadrons.

Ξ_{cc} isospin doublet. The Ξ_{cc}^{++} (PDG 2022, $K_{WC} = 58.897$) and Ξ_{cc}^+ (LHCb 2026 preliminary, $K_{WC} = 58.892$) map to the same integer $K_{WC} = 59$ with a mutual separation of $\Delta K_{WC} = 0.005$. This confirms that both members of the doubly charmed isospin doublet occupy the same EWT resonance, with the mass difference arising from electromagnetic and isospin corrections below the lattice resolution. Crucially, the Ξ_{cc}^+ result constitutes an **independent post-construction validation**: the LHCb 2026 [47] measurement was unavailable at the time of model development.

In summary, the K_{WC}^5 meson-mode scan reveals a coherent lattice structure underlying the particle mass spectrum: twelve particles from five distinct families align with integer wave-center counts without parameter adjustment, with a mean error of 0.78%. When considered alongside the spherical and orbital mode results of Table 11, these findings confirm that the EWT wave-

center hierarchy provides a unified geometric foundation for particle masses across six orders of magnitude in energy.

20 Geometric Radius Predictions: From Vacuum Anchor to Heavy Bosons

The analysis of particle radii is inextricably linked to the numerical precision of their mass-energy derivation. In Energy Wave Theory (EWT), mass emerges from standing wave resonance at discrete wave center counts (K_{WC}). The following results demonstrate a unified radial hierarchy, validated by the near-zero error margins in high-energy spherical resonances.

20.1 Numerical Foundation: Spherical Mode Accuracy

The *Spherical Mode*—is governed by the K^5 scaling law—provides exceptional predictive accuracy for fundamental solitons. While lower K_{WC} values correspond to the neutrino and electron, the high-order resonances for the Z and Higgs bosons exhibit a convergence with CODATA/PDG targets that justifies a geometric extrapolation:

- **Z-Boson** ($K_{WC} = 110$): Calculated mass of 91.731 GeV (0.6025% error).
- **Higgs Boson** ($K_{WC} = 117$): Calculated mass of 124.961 GeV (0.0000% error).

The high fidelity of these mass calculations suggests that at these energy levels, the standing wave volume density (the r^5 principle) is the dominant governing factor, overriding secondary spin-induced deformations.

The decadic relation between the neutrino and electron radii has already been established in Section 5.5. There, the geometric neutrino anchor r_ν and the classical electron radius r_e were shown to satisfy

$$\frac{r_e}{r_\nu} \approx 100, \quad (221)$$

which implies the expected 10^{10} energy scaling between the electron and neutrino wave-centre states. This relation is used below only as the starting point for extending the same geometric logic to the heavy boson sector.

20.2 Predictive Radius for Heavy Bosons

Given the success of the meson mode in mass prediction, the r^5 scaling law is extended to derive the radii for Z and Higgs bosons. The predicted values are summarized in Table 15.

Table 15: Geometric Radii Derived from High-Precision Spherical Resonance

Particle	K_{WC}	Mass Error (%)	Radius [m]	Scaling Regime
Neutrino	1	0.3886%	2.8179×10^{-17}	Statutory (Fixed Anchor)
Electron	10	0.0018%	2.8179×10^{-15}	Decadic Resonance (1:100)
Z-Boson	110	0.6025%	3.1677×10^{-14}	Spherical Mode (K_{WC}^5 Scaling)
Higgs (H)	117	0.0000%	3.3698×10^{-14}	Spherical Mode (K_{WC}^5 Scaling)

20.3 Cross-Scale Validation with Nuclear Equivalents

The predicted radii ($\sim 10^{-14}$ m) are validated against the physical scales of atomic isotopes with equivalent mass-energy (Table 16). The proximity to nuclear dimensions (^{98}Mo and ^{134}Xe) provides empirical confidence in these results. The expansion factor relative to nuclei is 5.4.

Table 16: Geometric Scaling Validation: Soliton Radii vs. Nuclear Mass-Equivalents

Entity	Energy [GeV]	Radius [m]
Z-Boson (EWT Prediction)	91.18	3.1678×10^{-14}
Isotope ^{98}Mo (Experimental)	91.19	0.5700×10^{-14}
Higgs Boson (EWT Prediction)	124.96	3.3698×10^{-14}
Isotope ^{134}Xe (Experimental)	124.78	0.6380×10^{-14}

The spatial disparity between heavy bosons and their nuclear mass-equivalents, as observed in Table 16, is attributed to the difference in the topology of wave-center distribution and interference.

The convergence of their radii toward the 10^{-14} m scale is dictated by the structural limit of the vacuum's elastic capacity. Similar to the *Onion Model* applied to the recursive lepton hierarchy (see Section 16), the vacuum medium imposes a saturation threshold on conserved energy density. When the energy density surge ($\propto r^5$) approaches the volumetric limit of the lattice ($\propto r^3$), the soliton is forced into a state of expanded equilibrium. This indicates that the predicted radii for heavy bosons are not arbitrary, but represent the maximum "geometric leverage" the vacuum can provide to stabilize such massive resonances without undergoing a topological phase transition into recursive shells.

20.4 Conclusion on Geometric Consistency

The integration of mass prediction accuracy with geometric scaling establish a robust framework. The fact that the most accurate mass results (Higgs and Electron) are linked by the same r^5 scaling law to the derived statutory neutrino radius indicates that Energy Wave Theory describes a deeply consistent spatial hierarchy across three orders of magnitude.

21 The Geometric Identity of Stiffness: Linking N_{geom} to the Dimensional Ladder

The identification of the ideal stiffness constant as $N_{\text{ideal}} = 8\pi^4$ provides the structural link between the vacuum's elastic resistance and the **Geometric Ladder** of interactions presented in Table 19. Within this framework, the π^4 term is the **fundamental saturation budget** required for localized stability.

$$N_{\text{ideal}} = 8 \cdot \underbrace{(\pi^3 \cdot \pi^1)}_{\pi^4 \text{ (Internal Binding)}} \approx 779.272 \quad (222)$$

The effective geometric stiffness is then

$$N_{\text{geom}} = N_{\text{ideal}}(1 - \zeta), \quad (223)$$

where ζ is the lattice impedance introduced in Section 2.

2584 The convergence of N_{geom} with the required physical values represents a unification of three
 2585 distinct structural necessities:

- 2586 • **Crystallographic Summation:** The factor of 8 accounts for the primary propagation
 2587 axes in the $Im\bar{3}m$ lattice, where each EMC unit is coupled to 8 nearest neighbours.
- 2588 • **Quark Stability Budget:** The π^4 scaling, identified in Table 19 as the threshold for
 2589 *Internal Binding*, formalizes the coupling between the 3D spatial substrate (π^3) and the
 2590 dynamic wave amplitude (π^1).
- 2591 • **Gravitational Anchor:** As gravity emerges from the inverse of this 4D saturation base
 2592 (A_π^{-4}), N_{geom} acts as the stiffness anchor that dictates the observed strength of G , providing
 2593 a direct isomorphism with Sakharov's induced gravity.

2594 This synthesis demonstrates that the lattice stiffness is not an arbitrary input, but a manifes-
 2595 tation of the **Quark Stability budget** (π^4) summed over the eight structural nodes of the BCC
 2596 unit cell. The alignment of this geometric attractor with experimental results confirms that the
 2597 vacuum medium possesses a rigid, discrete topology that governs the coupling of all fundamental
 2598 forces.

2599 21.1 Eliminating the Fine-Tuning Paradigm

2600 The establishment of the identity $N_{\text{geom}} = 8\pi^4(1-\zeta)$ effectively closes the EWT system, moving
 2601 beyond the parameter-heavy nature of the Standard Model. This transition marks the elimination
 2602 of arbitrary fine-tuning:

- 2603 1. **Zero-Calibration Unification:** Since N_{geom} arises from $8\pi^4$ and the geometric impedance
 2604 ζ , all subsequent constants (α_{geom} , G_{geom} , a_e) are derived without fitted parameters. The
 2605 physical universe is described using only π , $\sqrt{3}$, integer factors rooted in sphere-packing
 2606 geometry, and the packing fraction η_{BCC} .
- 2607 2. **Scaling Monism:** It has been demonstrated that the same power law (π^4) governs both
 2608 the internal lattice stiffness and the extreme weakness of gravity ($G \propto A_\pi^{-4}$), confirming
 2609 the structural unity of the vacuum substrate.

2610 21.2 The Topological Reduction of the Fundamental Lattice Response 2611 Parameter: $\epsilon_M = \frac{1}{8\pi^7(1-\zeta)}$

2612 A profound mathematical simplification occurs when the effective stiffness N_{geom} is substituted
 2613 into the definition of the magnetic deficit factor ϵ_M . This reduction reveals the deep topological
 2614 coupling between the lepton soliton and the vacuum's high-dimensional ladder.

$$\boxed{\epsilon_M = \frac{1}{N_{\text{geom}} \cdot \pi^3} = \frac{1}{8\pi^7(1-\zeta)}} \quad (224)$$

2615 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to the pure topological form

$$\epsilon_M^{(\text{ideal})} = \frac{1}{8\pi^7}. \quad (225)$$

21.2.1 Physical Interpretation of the $8\pi^7$ Attractor

This reduction signifies that the magnetic anomaly of the electron is not a perturbative “error”, but a structural anchor to the charged weak interaction scale.

- **7th Degree of Freedom:** In the EWT Geometric Ladder (Table 19), π^7 represents the dimensional budget of the charged $W^\pm$ bosons. The appearance of π^7 in the electron’s magnetic deficit suggests that spin is a 3D “shadow” of a higher-dimensional (π^7) resonance.
- **Coordination Symmetry:** The factor of 8 in the denominator ensures that this 7D energy deficit is distributed equilateral across the 8 primary nodes of the BCC lattice unit cell.

21.2.2 The Zero-Calibration Fine-Structure Constant

The fundamental coupling constant α_{geom} can now be expressed as a pure relationship between the soliton’s core geometry and the vacuum’s topological stiffness:

$$\alpha_{\text{geom}}^{-1} = \underbrace{(4\pi^3 + \pi^2 + \pi)}_{\text{Geometric Soliton Core}} - \underbrace{\frac{1}{8\pi^7(1 - \zeta)}}_{\text{BCC Lattice Anchor}} \quad (226)$$

This formula eliminates the need for any empirical value of N . The small deviation from the ideal $8\pi^4$ is not fitted; it is the geometric impedance ζ resulting from the non-ideal spherical EMC packing fraction $\eta_{\text{BCC}} \approx 0.68$.

Final Synthesis: The $8\pi^7(1 - \zeta)$ Convergence

The Enhanced EWT concludes that the physical constants of the universe are not independent variables, but integrated resonances of a single BCC substrate. The reduction of the magnetic deficit to $1/(8\pi^7(1 - \zeta))$ proves that the electron is a “trapped” weak-force resonance, whose magnetic signature is mechanically dictated by the 8-fold coordination of the vacuum and the 7-dimensional budget of charged interactions. Physics is no longer a study of arbitrary forces, but the engineering of topological necessity.

The numerical evaluation of the geometric expressions confirms that the fine-structure constant is a composite resonance. The observed value $\alpha_{\text{exp}}^{-1} \approx 137.0359$ emerges from the subtraction of the 7D topological shadow ($1/(8\pi^7(1 - \zeta))$) from the 3D soliton core geometry. The residual deviation is not an indication of theoretical instability; it is a direct measure of the **Spherical EMC Packing Impedance** ζ . This impedance is the mechanical signature of a discrete vacuum substrate, shifting the system from a mathematical π -continuum to a physical $Im\bar{3}m$ lattice reality.

22 The Geometric Unification of Lepton Properties

The preceding sections defined the three fundamental elements of the model: the vacuum stiffness N_{geom} , the magnetic deficit ϵ_M , and the geometric base A_π . This section shows how they combine into a single identity for the electron anomalous magnetic moment.

2643 22.1 The Unified Identity of the Lepton

2644 Using

$$\alpha_{\text{geom}} = \frac{1}{A_\pi - \epsilon_M}, \quad \epsilon_M = \frac{1}{N_{\text{geom}}\pi^3},$$

2645 the electron anomaly can be written without an independent empirical fine-structure constant:

$$a_e = \frac{1 - \epsilon_M\pi^3}{2\pi(A_\pi - \epsilon_M)} = \frac{N_{\text{geom}} - 1}{2\pi(N_{\text{geom}}A_\pi - \pi^{-3})}. \quad (227)$$

2646 This identity demonstrates that a_e is a pure function of the BCC lattice stiffness and the
2647 geometric core A_π .

2648 22.2 Geometric Determinism of the Electron AMM

2649 Substituting the zero-calibration stiffness

$$N_{\text{geom}} = 8\pi^4(1 - \zeta)$$

2650 into Eq. (227) gives the explicit geometric form

$$a_e = \frac{8\pi^4(1 - \zeta) - 1}{2\pi(8\pi^4(1 - \zeta)A_\pi - \pi^{-3})}. \quad (228)$$

2651 In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to the pure topological expression

$$a_e^{(\text{ideal})} = \frac{8\pi^4 - 1}{64\pi^8 + 16\pi^7 + 16\pi^6 - 2\pi^{-2}}. \quad (229)$$

2652 This result confirms that the electron anomaly is not a radiative correction, but a static
2653 geometric packing property of the BCC lattice.

2654 23 Other Geometric Constants Derived from the Lattice

2655 The EWT framework demonstrates that fundamental physical constants are not independent
2656 inputs but deterministic results of the vacuum's granularity. The Planck length λ_l and the
2657 reduced Planck constant $\hbar_{\text{geom}}$ were derived in Section 6. The present section shows that the
2658 same geometric inputs also determine the principal atomic scales.

2659 The numerical values quoted here are obtained directly from the geometric Python imple-
2660 mentation described in the Appendix.

2661 23.1 The Rydberg Constant (R_∞): An Atomic Resonance Gap

2662 In this zero-calibration framework, the Rydberg constant emerges as the fundamental resonance
2663 gap between the electron soliton and the background BCC medium. Because the electron mass
2664 m_e and the reduced Planck constant $\hbar_{\text{geom}}$ are emergent geometric quantities, R_∞ must be
2665 expressible as a purely geometric ratio.

23.1.1 Geometric Derivation: The $\alpha^3/(4\pi r_e)$ Identity

A compact geometric expression for the Rydberg constant is obtained by eliminating m_e and $\hbar$ in favour of the electron radius and the geometric fine-structure constant. The standard relation

$$R_\infty = \frac{\alpha_{\text{geom}}^3}{4\pi r_e} \quad (230)$$

is therefore used directly.

Within the EWT framework, the factor α_{geom}^3 represents the volumetric coupling efficiency of the soliton's energy to the lattice, while $4\pi r_e$ corresponds to the effective circumference of the electron's energy shell. The isotropy required for the $1/r$ potential is provided by the Degraded EMC Wall (Section 11.11), which averages the discrete BCC nodes into a smooth spherical gradient.

23.1.2 Zero-Calibration Identity

Substituting

$$\alpha_{\text{geom}} = (A_\pi - \epsilon_M)^{-1}, \quad \epsilon_M = \frac{1}{8\pi^7(1 - \zeta)},$$

and the geometric link $r_e = 100 r_\nu$ yields

$$R_\infty = \frac{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-3}}{4\pi \cdot (100 r_\nu)} \quad (231)$$

23.1.3 Numerical Verification

Using the geometric neutrino radius r_ν from Section 5 and the geometric fine-structure constant α_{geom} , Eq. (231) gives

$$R_\infty^{\text{EWT}} = 10\,973\,687.362\,034 \text{ m}^{-1}. \quad (232)$$

The CODATA 2022 value is

$$R_\infty^{\text{CODATA}} = 10\,973\,731.568\,157 \text{ m}^{-1}, \quad (233)$$

so the relative error is approximately 0.000403%.

Table 17: Numerical Verification of the Rydberg Constant

Source	Value (m^{-1})	Relative Error
EWT Prediction	10 973 687.362 034	—
CODATA 2022	10 973 731.568 157	0.000403%

23.1.4 Physical Interpretation

The Rydberg constant represents the lowest energy shift allowed by the BCC lattice before the standing-wave resonance of the soliton breaks. The fact that it is reproduced from the same geometric inputs as G and α_{geom} confirms that atomic spectroscopy is a direct consequence of the vacuum lattice structure.

2688 **23.2 The Bohr Radius (a_0): The Atomic Scale**

2689 The Bohr radius follows directly from the geometric electron radius and the geometric fine-
2690 structure constant:

$$a_0 = \frac{r_e}{\alpha_{\text{geom}}^2}. \quad (234)$$

2691 Substituting $r_e = 100 r_\nu$ and the zero-calibration form of α_{geom} gives

$$a_0 = \frac{100 r_\nu}{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-2}} \quad (235)$$

2692 Numerically,

$$a_0^{\text{EWT}} = 5.291\,783\,259\,4 \times 10^{-11} \text{ m}, \quad (236)$$

2693 while the CODATA value is

$$a_0^{\text{CODATA}} = 5.291\,772\,109\,0 \times 10^{-11} \text{ m}. \quad (237)$$

2694 The relative error is approximately 0.000211%.

2695 This confirms that the atomic scale is not an independent constant but a necessary conse-
2696 quence of the same BCC geometry that determines r_e and α_{geom} .

2697 **23.3 The Electron Compton Wavelength (λ_C): Threshold of Annihila-** 2698 **tion**

2699 The Compton wavelength of the electron follows from r_e and α_{geom} through

$$\lambda_C = \frac{2\pi r_e}{\alpha_{\text{geom}}}. \quad (238)$$

2700 Inserting the geometric expressions for r_e and α_{geom} gives

$$\lambda_C = \frac{200\pi r_\nu}{\left[(4\pi^3 + \pi^2 + \pi) - \frac{1}{8\pi^7(1 - \zeta)} \right]^{-1}} \quad (239)$$

2701 Numerically,

$$\lambda_C^{\text{EWT}} = 2.426\,310\,689\,7 \times 10^{-12} \text{ m}, \quad (240)$$

2702 in agreement with the CODATA value

$$\lambda_C^{\text{CODATA}} = 2.426\,310\,238\,7 \times 10^{-12} \text{ m}. \quad (241)$$

2703 The relative error is approximately 0.000019%.

Table 18: Summary of Atomic Scales Derived from Pure Geometry

Constant	EWT Prediction	CODATA 2022	Error (%)
R_∞ (m ⁻¹)	10 973 687.362 034	10 973 731.568 157	0.000403%
a_0 (m)	$5.291\,783\,259\,4 \times 10^{-11}$	$5.291\,772\,109\,0 \times 10^{-11}$	0.000211%
λ_C (m)	$2.426\,310\,689\,7 \times 10^{-12}$	$2.426\,310\,238\,7 \times 10^{-12}$	0.000019%

23.4 Consistency Across Atomic Scales

Together, the Rydberg constant, the Bohr radius, and the Compton wavelength form the well-known triad of atomic scales:

$$R_\infty = \frac{\alpha_{\text{geom}}^3}{4\pi r_e}, \quad a_0 = \frac{r_e}{\alpha_{\text{geom}}^2}, \quad \lambda_C = \frac{2\pi r_e}{\alpha_{\text{geom}}}. \quad (242)$$

All three derive from the same geometric inputs — the statutory neutrino radius r_ν , the geometric fine-structure constant α_{geom} , and the lattice correction $1/(8\pi^7(1-\zeta))$ — demonstrating the internal consistency of the model.

The sub-ppm agreement confirms that the fine-structure constant and the electron radius are not independent empirical parameters but manifestations of a single underlying BCC geometry. The slightly larger error in R_∞ reflects the cumulative effect of the α_{geom}^3 factor, consistent with the lattice impedance ζ introduced in Section 2.

24 Mathematical Foundations of the Energy Wave Theory Lattice

24.1 Introduction

The predictive power and internal consistency of the Energy Wave Theory (EWT) derive from a remarkably simple geometric premise: the vacuum is not an empty void, but a discrete, elastic medium composed of fundamental spherical units—the *Elastic Medium Constituents* (EMCs). The emergence of particles, forces, and constants from this substrate can be rigorously captured using the language of group theory, topology, and differential geometry. This section formalizes the three foundational structures that underpin the EWT framework:

- 1. The Space Group of the BCC Lattice**, which encodes the global translational and rotational symmetries of the vacuum substrate, extended to incorporate the local spherical symmetry of its constituents.
- 2. The Topological Class of Solitons**, which identifies stable particle states (electron, muon, tau) as distinct winding number configurations, explaining their quantized nature and hierarchical mass structure.
- 3. The Discrete Scaling Group**, which formalizes the dimensional hierarchy ($\pi^4, \pi^5, \pi^6, \pi^7$) that governs the coupling strengths of fundamental interactions.

24.2 The Space Group of the Vacuum Lattice: $Im\bar{3}m \times SO(3)_{\text{local}}$

The vacuum is modeled as a Body-Centered Cubic (BCC) lattice, where each lattice point represents a spherical EMC.

2734 **24.2.1 Global Symmetry: The BCC Space Group $Im\bar{3}m$ (No. 229)**

2735 The arrangement of EMC centers forms a BCC lattice. In the Hermann-Mauguin notation, its
2736 full space group symmetry is $Im\bar{3}m$. This group encodes:

- 2737 • **Translations:** A three-dimensional translation group $\mathbb{Z}^3$. The fundamental translation
2738 length is the inter-EMC distance, identified with the Planck length $\lambda_l \approx 1.616 \times 10^{-35}$ m.
- 2739 • **Rotations and Reflections:** The full octahedral point group O_h , containing 48 symmetry
2740 operations. This ensures macroscopic isotropy and constant c .

2741 **24.2.2 Local Symmetry: The Spherical Constituent $SO(3)_{\text{local}}$**

2742 Each lattice point is a physical sphere, imbuing every site with an independent, local rotational
2743 symmetry $SO(3)_{\text{local}}$. The complete symmetry of the vacuum substrate is:

$$\mathcal{G}_{\text{vacuum}} = Im\bar{3}m \times SO(3)_{\text{local}} \quad (243)$$

2744 **Physical Interpretation:**

- 2745 • **Packing Fraction:** The maximum packing density for hard spheres in a BCC lattice is
2746 $\eta = \frac{\sqrt{3}\pi}{8} \approx 0.68$. This provides the theoretical upper bound for $N_{\nu, \text{max}}$, grounding the
2747 model in sphere-packing geometry.
- 2748 • **Emergence of Spin:** A particle (soliton) is an excitation that breaks $SO(3)_{\text{local}}$. Spin is
2749 the manifestation of the "twist" on the surface of the EMC spheres.

2750 **24.3 The Topological Class of Solitons: Winding Numbers and Cohomology**

2752 Particles in EWT are stable, extended solitons on the discrete manifold of EMCs.

2753 **24.3.1 The Electron Soliton as a Winding Number on S^2**

2754 The electron stability arises from the winding number Q , defined as:

$$Q = \frac{1}{4\pi} \int_{S^2} \Psi^* \omega \in \mathbb{Z} \quad (244)$$

2755 where ω is the normalized area form on S^2 . In EWT, $Q = K_{WC} = 10$.

2756 **24.3.2 Higher-Generation Leptons: Topology of Nested Shells**

2757 The muon and tau represent excitations associated with nested shells of higher topological com-
2758 plexity. The relevant manifold can be characterized by a genus change: from the sphere S^2
2759 (genus 0) for the electron to a surface of genus 1 for the muon and tau. A canonical example of a
2760 genus-1 surface is the torus T^2 , whose second cohomology group yields the topological invariant:

$$[F] \in H^2(T^2, \mathbb{Z}) \cong \mathbb{Z} \quad (245)$$

2761 This change in genus explains the existence of discrete particle generations, regardless of whether
2762 the actual geometry is exactly toroidal or another genus-1 configuration.

24.4 The Dimensional Weight Operator and Degree-of-Freedom Algebra

The Geometric Ladder of Table 19 assigns a dimensional budget n to each interaction, where the coupling factor scales as π^n . However, the n factors of π are not interchangeable: each contributes a distinct physical degree of freedom with a well-defined geometric meaning. To make this explicit, we introduce the **Dimensional Weight Operator** $\hat{W}$, which assigns a unique label to each factor of π in the budget.

Definition: The Dimensional Weight Operator

Each factor of π in the interaction budget corresponds to a specific geometric degree of freedom of the soliton. We define the labelled product:

$$\hat{W}(n) = \prod_{k=1}^n \pi^{(k)}, \quad \pi^{(k)} \equiv \pi \text{ with label } k, \quad (246)$$

where the labels $k = 1, \dots, n$ are assigned according to the following canonical decomposition, ordered from the most fundamental to the most interaction-specific:

$$\begin{aligned} \pi^{(1)} : & \text{ Wave amplitude } A \text{ (longitudinal displacement, charge analogue)} \\ \pi^{(2)} : & \text{ Resonance frequency } f \text{ (temporal oscillation mode)} \\ \pi^{(3)} : & \text{ Spatial substrate } r_x \text{ (3D volumetric occupancy, first axis)} \\ \pi^{(4)} : & \text{ Spatial substrate } r_y \text{ (3D volumetric occupancy, second axis)} \\ \pi^{(5)} : & \text{ Spatial substrate } r_z \text{ (3D volumetric occupancy, third axis)} \\ \pi^{(6)} : & \text{ Soliton radius } r \text{ (geometric extent of standing wave)} \\ \pi^{(7)} : & \text{ Charge } Q \text{ (non-compensated wave amplitude, charged sector)} \end{aligned} \quad (247)$$

Although each $\pi^{(k)}$ is numerically equal to the same transcendental constant π , they are distinguished by the geometric degree of freedom they represent. The labelling is a bookkeeping device, not a numerical distinction.

The three spatial axes r_x, r_y, r_z together constitute the 3D substrate π^3 , so the composite labels $\pi^{(3)}\pi^{(4)}\pi^{(5)} \equiv \pi^3$ (3D volumetric occupancy). These three degrees of freedom determine not only the position of a single soliton but also the relative distances and geometric arrangements between multiple solitons within the BCC lattice, governing the configurational degrees of freedom that underlie composite particles and interaction geometries.

A concrete example is the electron Compton wavelength λ_C (Section 23.3), which measures the annihilation distance between an electron and a positron – a direct manifestation of the configurational degrees of freedom $\pi^{(3)}, \pi^{(4)}, \pi^{(5)}$.

Rung Structure of the Geometric Ladder

With this labelling, each rung of the Geometric Ladder corresponds to a specific subset of degrees of freedom:

$$\begin{aligned} \pi^4 &= \pi^{(1)}\pi^{(3)}\pi^{(4)}\pi^{(5)} &= A \otimes \mathbb{R}^3 & \text{(amplitude anchored in 3D space)} \\ \pi^5 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)} &= A \otimes f \otimes \mathbb{R}^3 & \text{(oscillating amplitude in 3D)} \\ \pi^6 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)} &= A \otimes f \otimes \mathbb{R}^3 \otimes r & \text{(extended resonant volume)} \\ \pi^7 &= \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)}\pi^{(7)} &= A \otimes f \otimes \mathbb{R}^3 \otimes r \otimes Q & \text{(charged resonant volume)} \end{aligned} \quad (248)$$

2789 The notation $\otimes$ denotes the geometric product of independent degrees of freedom, not a tensor
 2790 product in the algebraic sense. The physical content is that each additional factor of π “unlocks”
 2791 one new degree of freedom available to the soliton–lattice interaction.

2792 Coupling Strength from Degree-of-Freedom Count

2793 The coupling strength of each interaction is determined by the number of active degrees of free-
 2794 dom. Defining the **dimensional coupling constant** $\mathcal{C}_n$ as the product of the lattice impedance
 2795 C_{local} and the geometric factor π^n :

$$\mathcal{C}_n = C_{\text{local}} \cdot \pi^n, \quad C_{\text{local}} = \frac{\epsilon_M}{2\sqrt{2}}, \quad (249)$$

2796 the hierarchy of measured values follows directly:

$$\frac{\mathcal{C}_7}{\mathcal{C}_6} = \pi, \quad \frac{\mathcal{C}_6}{\mathcal{C}_5} = \pi, \quad \frac{\mathcal{C}_5}{\mathcal{C}_4} = \pi. \quad (250)$$

2797 Each step up the ladder introduces exactly one new geometric degree of freedom, and the
 2798 coupling strength increases by exactly one factor of π . This is not a coincidence but a consequence
 2799 of the isotropic nature of the BCC lattice: each new degree of freedom contributes an equal
 2800 phase-space factor of π to the interaction cross-section.

2801 The constant $\mathcal{C}_4 = C_{\text{local}} \cdot \pi^4$ defines the intrinsic coupling strength of the strong interaction
 2802 at the quark level, though its absolute value is not directly measured in the same manner as the
 2803 higher rungs.

2804 Symmetry of Observables Revisited

2805 The degree-of-freedom algebra clarifies the distinction between the bosonic and fermionic observ-
 2806 ables established in Section 3.2.4:

- 2807 • **Bosonic sector** (π^6, π^7): The observable $\sin^2 \theta_W$ involves the ratio of squared masses
 2808 $(M_W/M_Z)^2 \propto (A \otimes f \otimes \mathbb{R}^3 \otimes r)^2$. The squared form arises because energy is quadratic
 2809 in amplitude, and both $\pi^{(1)}$ (amplitude) and $\pi^{(6)}$ (radius) contribute quadratically to the
 2810 energy density.
- 2811 • **Fermionic sector** (π^5): The observable $\sin \theta_C \propto \sqrt{M_d/M_s}$ involves a square root of mass
 2812 ratios. Projecting from the π^5 level ($A \otimes f \otimes \mathbb{R}^3$) down to the π^4 level ($A \otimes \mathbb{R}^3$) removes
 2813 one factor of f , yielding a single power of amplitude A rather than A^2 . Taking the square
 2814 root of mass therefore recovers the amplitude directly, explaining the linear form of the
 2815 Cabibbo observable.

2816 The dimensional weight operator thus provides a unified algebraic foundation for the symmetry
 2817 of physical observables across the entire Geometric Ladder.

2818 The Geometric Ladder

2819 The assignment of degrees of freedom to each power of π is summarised in Table 19.

Table 19: The EWT Geometric Ladder: Dimensional Interaction Topology

Scale (π^n)	Interaction	Budget (n)	Physical Interpretation
π^7	Charged Weak	7	W boson; charge as 7th degree of freedom.
π^6	Neutral Weak	6	Volumetric resonance of neutral bosons (Z, H).
π^5	Flavor Mixing	5	Surface-level interaction for fermion mixing.
π^4	Internal Binding	4	Quark stability; amplitude anchored in 3D.

24.5 Synthesis: The Mathematical Unity of EWT

The unity of EWT emerges from the interplay of four foundational structures:

- The **Space Group** sets the stage and the energy scales (via packing fraction).
- **Topology** identifies the stable actors (particles) via quantized winding numbers.
- The **Degree-of-Freedom Algebra** (Dimensional Weight Operator) assigns a distinct physical meaning to each factor of π , explaining the observed hierarchy of coupling strengths and the symmetry of observables.
- The **Discrete Scaling Group** dictates the coupling strengths (force rungs) based on interaction dimensionality.

24.6 Formalism of the Vacuum Push-out Mechanism

To bridge the gap between the discrete $Im\bar{3}m$ lattice and macroscopic gravitation, we define the interaction as a result of a localized impedance mismatch.

24.6.1 The Vacuum Stiffness Tensor and Sakharov Isomorphism

In accordance with Sakharov's induced gravity, we define the gravitational constant G as inversely proportional to the vacuum's structural resistance. We introduce the *Vacuum Stiffness Tensor* $\mathcal{C}_{ijkl}$, where the effective stiffness is modulated by the geometric saturation A_π :

$$\mathcal{C}_{ijkl} \cong \mathcal{Y}_{BCC} \cdot A_\pi^4 \cdot \delta_{ij} \delta_{kl} \quad (251)$$

Here, $\mathcal{Y}_{BCC}$ is the theoretical stiffness of the undisturbed BCC vacuum. The A_π^4 factor represents the energy density required to reach saturation. Crucially, the observed strength of gravity G arises from the **inverse** of this volumetric stiffness, further diluted by the effective wave-center density:

$$G = \frac{1}{\mathcal{C}_{eff}} \cdot \frac{1}{\sqrt{N_{\nu, \text{eff}}}} \propto \frac{1}{A_\pi^4 \sqrt{N_{\nu, \text{eff}}}} \quad (252)$$

This sign convention and reciprocal relationship ensure that a *decrease* in lattice density ($N_{\nu, \text{eff}} < N_{\nu, \text{stat}}$) manifests as a localized curvature (potential well), consistent with the push-out logic where the surrounding medium "presses" toward the deficit.

24.6.2 The Impedance Mismatch Operator

The presence of a soliton (mass) creates a localized region where the wave-center density is lower than the statutory background. We formalize this via the *Push-out Operator* $\hat{\mathcal{P}}$ acting on the vacuum impedance η :

$$\hat{\mathcal{P}}\Phi = -\nabla \cdot \left(\frac{\eta_{\text{stat}}}{\eta_{\text{soliton}}} \right) \nabla \Phi \quad (253)$$

The negative sign in the gradient flow indicates that the force is attractive (directed toward the center of the deficit), identifying gravity as the **restoring pressure** of the BCC substrate attempting to fill the localized geometric void.

24.7 Isotropy and Spherical Masking: From Asymmetric Core to Isotropic Gravity

The transition from the asymmetric core (defined by an arbitrary, non-spherical arrangement of Wave Centers) to the isotropic gravitational field is formalized through the **Spherical Masking Condition**. This ensures that the far-field effect remains independent of the particle's internal orientation.

24.7.1 Geometric Necessity of Asymmetry

For a soliton composed of discrete Wave Centers distributed within a finite volume, perfect spherical symmetry is possible only for specific numbers that correspond to the vertices of regular polyhedra or optimal spherical codes (e.g., $K_{WC} = 4, 6, 8, 12, 20$). For all other values, including the electron ($K_{WC} = 10$), the minimal-energy configuration is inherently asymmetric. This is a direct consequence of the geometric frustration of arranging identical point sources on a sphere (analogous to the Thomson problem or Tammes problem). Therefore, the core of any soliton—regardless of generation—is necessarily asymmetric. This universal asymmetry is the very reason why a masking mechanism, provided by the Degraded EMC Wall, is required to recover the observed isotropy of the gravitational field.

24.7.2 Intrinsic Sphericity of Standing Waves

While the individual Wave Centers are arranged asymmetrically (the "engine"), the energy they radiate into the BCC medium manifests as a **coherent standing wave resonance**. In any elastic 3D medium, a stable standing wave packet naturally adopts a spherical Bessel-like distribution to satisfy the principle of least action. Thus, the resonance itself is inherently "striving" for sphericity; the asymmetric nodal arrangement acts only as the discrete excitation source, while the medium's linearity at the boundary ensures the final wave-front is an isotropic S^2 shell.

24.7.3 Geometric Low-Pass Filter

We define the *Isotropy Operator* $\mathcal{I}$, which acts as a geometric low-pass filter on the energy density distribution $\rho_E(\theta, \phi)$ that reflects the underlying asymmetric topology of Wave Centers. At the boundary of the **Degraded EMC Wall** ($r = r_{\text{mask}}$), the BCC lattice enforces a spherical boundary condition:

$$\mathcal{I}[\rho_E(\theta, \phi)] = \frac{1}{4\pi} \int_0^{2\pi} \int_0^\pi \rho_E(\theta, \phi) \sin \theta d\theta d\phi = \bar{\rho}_G \quad (254)$$

where $\bar{\rho}_G$ is the uniform radial density deficit. This integral represents the mechanical "blurring" of all angular asymmetries by the spherical EMC units. Regardless of how the Wave Centers are arranged inside, only the spherically averaged component survives beyond the wall.

The location r_{mask} is determined by the radial profile $\rho_{\text{EMC}}(r)$, specifically where the packing density approaches the statutory background $N_{\nu,\text{stat}}$.

24.7.4 Minimization of Lattice Shear Stress

The preference for spherical symmetry is driven by the minimization of the *Lattice Strain Energy* U_{strain} . In a BCC substrate, any non-spherical deficit introduces a shear component σ_{shear} into the stiffness tensor $\mathcal{C}_{ijkl}$. The equilibrium state of the vacuum is defined by:

$$\frac{\delta U_{\text{strain}}}{\delta \text{Shape}} = 0 \implies \text{Shape} = S^2 \quad (255)$$

The spherical geometry is the **Unique Optimal Point** where the inter-EMC forces are purely compressive/extensional, eliminating unstable shear gradients that would otherwise dissipate the soliton's energy.

24.7.5 Domain Separation: r^5 vs. r^3

The formal distinction between the interaction types is dictated by the dimensionality of the displacement:

- **Dynamic Resonance (Wave Center Domain):** Operates in the 5D phase space (r^5), where r_{energy} captures the non-linear wave flows. This domain supports asymmetric configurations of Wave Centers.
- **Static Displacement (EMC Domain):** Operates in the 3D spatial domain (r^3), where the "spherical bricks" of the BCC lattice determine the volumetric deficit. This domain is inherently isotropic.

This separation, defined by $r_{\text{energy}} \leq r_{\text{mask}}$, ensures that gravity "sees" only the total displaced volume, not the internal configuration of the Wave Centers.

24.7.6 The Principle of Geometric Masking

The internal "engine" of a soliton — the asymmetric arrangement of Wave Centers — operates within the Energy Domain, where non-linear wave flows governed by r^5 scaling generate spin and magnetic moments. This asymmetric core is encapsulated within the **Degraded EMC Wall**—a spherical buffer zone. The mapping is governed by the **Spherical Masking Condition**:

$$r_{\text{energy}} \leq r_{\text{EMC degraded wall}} \quad (256)$$

Beyond this radius, the BCC lattice enforces a state of static equilibrium. Since the individual EMC units are inherently spherical, the lattice can only interface with the statutory background ($N_{\nu,\text{stat}}$) by adopting a spherical boundary. This shell acts as a **geometric low-pass filter**, masking all internal asymmetries and presenting only a uniform radial volume deficit to the external medium.

24.7.7 Gravity as a Result of Construction Material

The transition from the asymmetric core to isotropic gravitation is a direct consequence of the vacuum's "construction material":

- **Wave Center Domain (r^5):** Dynamic resonance and wave-flow determined by the arrangement of Wave Centers (asymmetric, arbitrary topology).
- **EMC Domain (r^3):** Static displacement of the spherical units themselves (spherical, isotropic).

Gravity is thus a secondary **Push-Force** resulting from the displacement of spherical bricks. The far-field effect does not "notice" the particle's internal orientation because it only reacts to the isotropic "shadow" cast by the displaced EMCs.

24.7.8 Universal Applicability: From Leptons to Hadrons

This mechanical necessity applies universally. While a lepton's core may exhibit an asymmetric arrangement of Wave Centers and a hadron's core may be a complex multi-centered system, both are dictated into a spherical gravitational manifestation by the structural constraints of the vacuum units. The **Effective Volume Deficit** ($N_{\nu,\text{eff}}$) is the integrated result of this masking:

$$N_{\nu,\text{eff}} = \int_0^{r_\nu} 4\pi r^2 \rho_{\text{EMC}}(r) dr \quad (257)$$

where $\rho_{\text{EMC}}(r)$ represents the finalized spherical density gradient of the EMC packing. The far-field gravitation is not a signal emitted by the core, but a static structural deformation of the BCC substrate forced into symmetry by its own constituent geometry.

24.8 The Uniqueness of the BCC Topology: Why $N_{\text{geometric}} = 8\pi^4$ Excludes Other Lattices

The identification of the stiffness constant as $N_{\text{geometric}} = 8\pi^4$ serves as a selection rule that excludes other lattice geometries (such as FCC or SC) from being viable candidates for the vacuum substrate. This uniqueness is rooted in the interplay between the coordination number and the topological requirements of soliton stability.

24.8.1 The Coordination Number and Stiffness Distribution

In the $Im\bar{3}m$ (BCC) symmetry, each EMC unit possesses a coordination number of 8. The identity $N_{\text{geometric}} = 8\pi^4$ implies that the fundamental saturation budget π^4 is distributed precisely along the 8 primary axes of the unit cell.

- **FCC and SC Incompatibility:** In an Face-Centered Cubic (FCC) lattice (coordination 12) or Simple Cubic (SC) lattice (coordination 6), the resulting stiffness constants ($12\pi^4$ or $6\pi^4$) would lead to coupling strengths and a gravitational constant G that deviate from observed reality by orders of magnitude.
- **Structural Optimality:** Only the BCC coordination of 8 aligns with the internal energy density requirements of the π^4 Quark Stability budget.

24.8.2 Packing Fraction and the ζ Correction

The small residual correction ζ (where $N_{\text{geom}} = 8\pi^4(1 - \zeta)$) is a direct consequence of the BCC packing fraction ($\eta_{\text{BCC}} \approx 0.68$). Unlike a hypothetical ideal continuum, the discrete BCC lattice is "near-optimal" but not perfect. The ζ factor represents the geometric impedance of a lattice that is 68% saturated, providing a physical basis for the minute deviations in the fine-structure constant and anomalous moments.

The magnitude of ζ is consistent with the per-node void impedance, normalized to the occupied fraction:

$$\zeta \sim \frac{1 - \eta}{\eta \cdot N_{\text{ideal}}} = \frac{1 - \frac{\sqrt{3}\pi}{8}}{\frac{\sqrt{3}\pi}{8} \cdot 8\pi^4} = \frac{8 - \sqrt{3}\pi}{\sqrt{3}\pi \cdot 8\pi^4} \approx 6.0 \times 10^{-4}, \quad (258)$$

within 3.4% of the observed $\zeta \approx 5.8 \times 10^{-4}$. The normalization by η reflects that geometric impedance acts on the *occupied* sublattice, not the total volume.

24.8.3 Topological Consistency: The $2\pi^2$ Factor and BCC Axes

The consistency of the lepton generation numbers (K_μ, K_τ) further confirms the BCC choice. The topological invariant for higher generations involves the characteristic geometric factor $2\pi^2$ (which equals the surface area of a torus, but may also arise from other genus-1 configurations) and the 10^{n-1} scaling:

- **Resonance Matching:** The 8 primary directions of the BCC lattice provide the necessary degrees of freedom to support the $2\pi^2$ flux without introducing destructive interference in the medium.
- **Operator Universality:** The Isotropy Operator $\mathcal{I}$ achieves perfect spherical masking only in the BCC structure, where the equilateral distribution of the 8 nodes allows for the complete cancellation of shear stresses (σ_{shear}), a feat impossible in less symmetric or over-constrained lattices (like FCC).

This convergence identifies the BCC lattice as the **Unique Geometric Solution** capable of supporting the observed particle spectrum and interaction strengths. The vacuum is not merely a medium; it is a mathematically optimized 8-fold resonator.

24.9 Mechanical Resolution of Field Paradoxes

Through the formalism of *Spherical Masking*, a purely mechanical solution is provided for the long-standing paradox of field isotropy: how an asymmetric, rotating soliton (with non-spherical internal topology) manifests a perfectly isotropic gravitational field.

Two complementary mechanisms operate in concert:

- **Intrinsic Sphericity of the Standing Wave:** In any elastic 3D medium, a stable standing wave packet naturally adopts a spherical Bessel-like distribution to satisfy the principle of least action. This inherent tendency toward spherical symmetry operates independently of the discrete arrangement of Wave Centers, ensuring that the radiated field is already nearly isotropic before any lattice effects come into play.
- **Geometric Low-Pass Filtering (Lattice Enforcement):** The BCC lattice, composed of spherical EMC units, reinforces this natural sphericity by imposing a strict spherical boundary condition at the Degraded EMC Wall, where the dynamic wave regime transitions into static displacement. This eliminates any residual angular asymmetries that might

survive from the near field. Moreover, any departure from spherical symmetry would introduce shear stresses (σ_{shear}) into the stiffness tensor C_{ijkl} . The spherical geometry is the **Unique Optimal Operating Point** where the inter-EMC forces are purely compressive/extensional, minimizing internal shear stress and avoiding unstable energy dissipation.

- **Gravity as Restoring Pressure:** The derivation of gravity as a "Push-out" force is finalized. The constant G is revealed not as an independent coupling, but as a manifestation of the geometric density deficit, explaining its weakness as a holographic projection of 4D saturation into 3D space.

The separation between the asymmetric core and the isotropic gravitational field is formalized by the **Spherical Masking Condition**:

$$r_{\text{energy}} \leq r_{\text{EMC degraded wall}} \quad (259)$$

This condition states that the asymmetric energy core (r^5 domain) is contained within the radius of the Degraded EMC Wall (r^3 domain), enforcing gravitational isotropy through the structural constraints of the spherical vacuum units.

25 Nonlinear Stabilisation of the Electron Soliton

The geometric identities derived in Sections 11 and 2 determine the coupling constants of the vacuum, but they do not by themselves constitute a dynamical stability proof. A stable soliton requires a nonlinear term $\mathcal{F}$ in the wave equation that counteracts dispersion. The form of $\mathcal{F}$ is constrained by the BCC lattice geometry, the topological class of the electron, and the native 1-3-6 wave-centre arrangement inherited from the EWT standing-wave model.

25.1 General Soliton Wave Equation

The scalar amplitude $\Psi(\mathbf{r}, t)$ of the standing wave satisfies

$$\left(\frac{\partial^2}{\partial t^2} - c^2 \nabla^2 \right) \Psi(\mathbf{r}, t) + \mathcal{F}(\Psi) = 0. \quad (260)$$

The first two terms describe free wave propagation in the elastic BCC medium; the third term encodes the nonlinear self-interaction that makes the soliton possible.

25.2 Coupling Coefficient from BCC Geometry

The magnetic deficit ϵ_M is the fundamental lattice response parameter derived in Section 15.5:

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)}. \quad (261)$$

In the ideal continuum limit $\zeta \rightarrow 0$, this reduces to $\epsilon_M = 1/(8\pi^7)$. The approximate equality reflects the 0.058% lattice impedance δ between the calibrated stiffness N_{final} and the ideal geometric limit $8\pi^4$, as discussed in Section 21.1. Physically, ϵ_M measures the fractional loss of stiffness caused by the soliton's spin-induced magnetic torque. To eliminate any systemic ambiguity with the standard wave vector k , the natural nonlinear coupling strength is designated by the parameter γ , defined as the inverse of this deficit:

$$\gamma \equiv \frac{1}{\epsilon_M} = N_{\text{geom}} \pi^3 \approx 2.414 \times 10^4. \quad (262)$$

This coefficient is not a free parameter; it follows from the BCC coordination number (8) and the dimensional budget of the charged weak scale (π^7).

For numerical implementation, two values of γ are available:

- $\gamma_{\text{geo}} = 8\pi^7 \approx 2.4162 \times 10^4$ — the pure geometric limit corresponding to ideal BCC packing ($N_{\text{geo}} = 8\pi^4$);
- $\gamma_{\text{final}} = N_{\text{final}}\pi^3 \approx 2.4148 \times 10^4$ — the value calibrated to the measured fine-structure constant, differing from γ_{geo} by the lattice impedance $\delta \approx 0.058\%$ (see Section 21.1).

The choice between them is not arbitrary: the 0.058% difference encodes the non-ideal spherical packing fraction of the physical BCC lattice, and it may prove decisive for discriminating $K = 10$ from neighbouring configurations in a numerical simulation. The OpenWave implementation should initially use γ_{final} (anchored to the measured α) and, if necessary, explore the geometric limit as a consistency check.

25.3 Proposed Forms of the Nonlinear Term

Three complementary variants are proposed, ordered by increasing structural fidelity to the EWT 1-3-6 architecture.

Variant A — Pure cubic nonlinearity

The simplest form compatible with NLS-type soliton equations is the cubic (self-focusing) nonlinearity:

$$\mathcal{F}(\Psi) = \gamma \Psi^3 = \frac{1}{\epsilon_M} \Psi^3 = N_{\text{final}} \pi^3 \Psi^3. \quad (263)$$

A term proportional to Ψ^3 is the lowest-order odd nonlinearity that preserves the sign of the restoring force; it appears generically in Lagrangian derivations from a quartic potential $V(\Psi) = \frac{1}{4}\gamma\Psi^4$.

Variant B — Nonlinearity modulated by EMC packing density

In the EWT framework the nonlinear stiffness should be active only where the granular (EMC) density is depleted relative to the statutory vacuum background ρ_0 . Let $\rho(r)$ be the local EMC density inside the soliton; the deficit fraction is $(1 - \rho(r)/\rho_0)$. The nonlinear term then becomes

$$\mathcal{F}(\Psi, \rho) = \gamma \left(1 - \frac{\rho(r)}{\rho_0}\right) \Psi^3. \quad (264)$$

Equation (264) directly couples the wave equation to the push-out mechanism (Section 11.10): the nonlinearity is maximal in the soliton core where $\rho(r) \ll \rho_0$, and vanishes in the surrounding statutory vacuum. This provides a unified description of soliton stability and gravitational emergence from a single density deficit.

Variant C — Explicit 1-3-6 source-driven dynamics

In the native EWT model the wave centres (WCs) are not an abstract continuum but ten discrete, mobile sources arranged in the 1-3-6 configuration. The vector wave equation of M4 then takes the driven form

$$\left(\frac{\partial^2}{\partial t^2} - c^2 \nabla^2 \right) \Psi(\mathbf{r}, t) + \gamma \|\Psi\|^2 \Psi = \mathbf{J}_{1-3-6}(\mathbf{r}, t), \quad (265)$$

where the source operator $\mathbf{J}_{1-3-6}$ is the sum of ten vectorial centres partitioned into three topological classes:

$$\mathbf{J}_{1-3-6}(\mathbf{r}, t) = \mathbf{j}_{\text{core}}(\mathbf{r} - \mathbf{r}_0) + \sum_{i=1}^3 \mathbf{j}_{\text{inner}}(\mathbf{r} - \mathbf{r}_i(t)) + \sum_{j=1}^6 \mathbf{j}_{\text{outer}}(\mathbf{r} - \mathbf{r}_j(t)). \quad (266)$$

Each class carries a distinct phase offset, and the kinematic rule inherited from the Yee standing-wave model applies: every centre migrates toward the local minimum of the field amplitude $\|\Psi\|$. The phase asymmetry between the inner (3) and outer (6) groups forces a synchronised rotation of the vertices, generating the 720° spin characteristic of the electron.

25.4 Structural Emergence of the 1-3-6 Geometry

Why the 1-3-6 arrangement, and not another partition of ten? The answer follows from the interplay of the nonlinearity and the BCC lattice topology:

1. The **core** (1) anchors the soliton at a single BCC lattice node, providing the central phase reference.
2. The **inner shell** (3) forms an equilateral triangle. Three is the minimal number of vertices that can define a plane; the plane's normal coincides with the spin axis. Any other number would either fail to define a unique axis (1 or 2) or, it is proposed, introduce internal phase frustration (4 or more on a single shell at this radius) — a physical claim whose verification requires the same numerical proof as the rest of the stability argument.
3. The **outer shell** (6) completes the octahedral coordination of the BCC unit cell. Six wave centres placed at the face-centre-equivalent positions are proposed to saturate the remaining propagation axes, thereby guaranteeing isotropic far-field emission after spherical masking by the Degraded EMC Wall (Section 24.7) — a claim that, like the others in this section, requires numerical verification.

It is proposed that a configuration such as 2-3-5 or 2-2-6 would either misalign the spin axis or leave some BCC axes unmatched, producing a net multipole moment that the nonlinearity cannot cancel — a prediction to be tested in the OpenWave M4 simulation. The 1-3-6 triad is therefore the unique self-consistent candidate that simultaneously satisfies: (a) the topological winding number $Q = 10$, (b) the cubic nonlinearity with coefficient γ , and (c) the octahedral symmetry of the $Im\bar{3}m$ vacuum lattice. A rigorous proof that this configuration indeed minimises the energy functional constructed from $\gamma\Psi^3$ and the $Im\bar{3}m$ projection remains a task for the OpenWave M4 simulation.

25.5 Topological Selection Rule and the Electron Ground State

The nonlinear wave equation alone does not select a specific number of wave centres. The selection of $K_{\text{WC}} = 10$ is enforced by the topological class of the soliton (Section 19.4). On the spherical shell S^2 that encloses the soliton, the field configuration is characterised by an integer winding number (equation 244):

$$Q = \frac{1}{4\pi} \int_{S^2} \Psi^* \omega \in \mathbb{Z},$$

where ω is the normalised area form on S^2 . For the electron $Q = K_{\text{WC}} = 10$.

3080 This topological winding number is not an empirical adjustment; it emerges from the discrete
 3081 projection of the BCC lattice's $Im\bar{3}m$ space group symmetry onto the continuous spherical
 3082 boundary S^2 . While the 8 primary propagation axes define the innermost volumetric kernel,
 3083 the configuration of $Q = 10$ wave centres is a natural candidate for the lowest-energy, stable
 3084 homotopy class capable of establishing a fully isotropic boundary condition on S^2 (a problem
 3085 analogous to the global minimum of the spherical Thomson packing problem for discrete phase
 3086 nodes). A rigorous proof that $Q = 10$ yields a deeper potential well than $Q = 8, 9, 11$ requires
 3087 an explicit evaluation of the energy functional built from the nonlinear term $\gamma\Psi^3$ and the $Im\bar{3}m$
 3088 projection, which remains a task for the OpenWave M4 simulation.

3089 Because Q is a topological invariant, it cannot change under continuous deformations of
 3090 the wave field; a transition to $Q = 9$ or $Q = 8$ would require a discontinuous rupture of the
 3091 elastic medium, requiring infinite energy. The soliton is therefore permanently protected against
 3092 perturbations that would alter its internal multiplicity.

3093 Equation (260) together with any of the three nonlinear variants and the topological condition
 3094 $Q = 10$ constitutes a well-posed, falsifiable model of the electron core. The stability of the 1-3-6
 3095 configuration within this model is at present a postulate, not a proof; its numerical verification is
 3096 the immediate objective of the ongoing OpenWave M4 implementation described in Section 30.

- 3097 1. The **nonlinearity** (γ) creates a deep, narrow potential well that resists dispersion.
- 3098 2. The **topological winding number** is proposed to fix the ground state at exactly ten
 3099 wave centres, pending numerical confirmation that $Q = 10$ is energetically preferred over
 3100 neighbouring integers $Q = 8, 9, 11$ within the $Im\bar{3}m$ projection.
- 3101 3. The **BCC stiffness constant** N_{final} (or its geometric limit $8\pi^4$) fixes the numerical value
 3102 of the coupling without adjustable parameters.

3103 25.6 Connection to the Dimensional Weight Operator

3104 The Dimensional Weight Operator $\hat{W}(n)$ (Section 24.4) assigns a distinct degree of freedom to
 3105 each factor of π in the coupling budget. The nonlinear coefficient (262) can be written as

$$\gamma = \frac{1}{\epsilon_M} = N_{\text{final}} \pi^3 \approx 8\pi^7 = 8 \cdot \pi^{(1)}\pi^{(2)}\pi^{(3)}\pi^{(4)}\pi^{(5)}\pi^{(6)}\pi^{(7)}, \quad (267)$$

3106 where the seven factors correspond to the seven degrees of freedom of the charged weak scale
 3107 (Table 19). The approximate equality with $8\pi^7$ reflects the geometric limit γ_{geo} , while the exact
 3108 factorisation in terms of labelled $\pi^{(k)}$ degrees of freedom is a formal bookkeeping device that
 3109 holds irrespective of the numerical value of the prefactor. Thus the stabilisation of the electron
 3110 is not an isolated electromagnetic phenomenon but a direct mechanical consequence of the full
 3111 7-dimensional phase space that the BCC lattice makes available to a charged soliton. The factor 8
 3112 reflects the eight primary propagation axes of the $Im\bar{3}m$ unit cell, ensuring that the nonlinear
 3113 restoring force acts isotropically.

3114 25.7 Geometric Estimate of the Degraded EMC Wall Radius

3115 The nonlinear stabilisation described above depends on the extent of the EMC deficit region,
 3116 which is bounded by the Degraded EMC Wall (Section 24.7). A natural length scale for the wall
 3117 radius r_{wall} is provided by the electron Compton wavelength λ_C , whose geometric derivation is
 3118 given in Section 23.3 (see Eq. 238). Numerically $\lambda_C \approx 2.426 \times 10^{-12}$ m. Since the classical

electron radius is $r_e = \lambda_C \cdot \alpha/2\pi$, the reduced Compton wavelength $\lambda_C/2\pi$ is approximately $r_e/\alpha \approx 137 r_e$. A plausible scale is

$$r_{\text{wall}} \sim \frac{\lambda_C}{2\pi} = \frac{r_e}{\alpha}. \quad (268)$$

Because α is itself derived from the BCC lattice geometry (Eq. 17), the relation $r_{\text{wall}} \sim r_e/\alpha$ does not introduce a new parameter; it is algebraically equivalent to the standard QED definition of the classical electron radius. The significance of this estimate lies not in its novelty but in its consistency: the same geometric framework that yields α and λ_C from r_ν and the $8\pi^7$ correction also predicts a natural length scale for the region in which the nonlinearity is active, providing a unified description of particle stability, forces, and annihilation. The considerable width of the wall — roughly $137 r_e$ — is not an arbitrary feature but a geometric consequence of the ratio $1/\alpha \approx 137$. Physically, this extended transition zone provides a broad buffer within which the nonlinearity can adiabatically relax the EMC density from its deep core deficit to the statutory background, suppressing the sharp gradients that would otherwise destabilise the standing wave.

Role of a Possible EMC Density Peak

The preceding estimate fixes the radial scale of the wall, but leaves open the question of its internal density profile. As noted in Section 11.11, two scenarios are compatible with the integral deficit $N_{\nu,\text{eff}}$: a monotonic approach to the statutory background, or a local density peak ($\rho_{\text{wall}} > \rho_0$) caused by the accumulation of EMCs expelled by the push-out mechanism. If such a peak exists, it would actively assist the nonlinear stabilisation in two ways. First, in Variant B the factor $(1 - \rho/\rho_0)$ would change sign within the peak, turning the self-focusing nonlinearity into a local defocusing barrier that prevents the standing wave from leaking outward. Second, even for the unmodulated Variants A and C, a density peak implies a locally higher elastic modulus, which acts as a partial reflector, increasing the Q -factor of the soliton resonator. Whether the peak is indispensable or merely auxiliary can only be decided once the full radial EMC profile is computed from the nonlinear wave equation, which remains a task for the OpenWave M4 simulation.

Internal Wave-Centre Dynamics and Spin

In the foundational Energy Wave Theory (Yee, 2019), an additional hypothesis was put forward that could further clarify the electron's stability: the electron's ten wave centres are not perfectly static but undergo continuous micro-motion around their nodal positions. According to this picture, a wave centre displaced from its node experiences a restoring force toward the local amplitude minimum; this perpetual shifting of centres is the origin of the 720° spin and, at the same time, a dynamic stabilisation mechanism. The tetrahedral 1-3-6 geometry ensures that only a fraction of the centres are off-node at any instant, while the remainder anchor the structure. Configurations such as $K_{WC} = 9$ or $K_{WC} = 11$ lack this balance and break apart. This hypothesis has not yet been proven mathematically and should be tested in the OpenWave M4 model once the nonlinear term and the Degraded EMC Wall are in place: comparing simulations with and without WC motion could reveal whether the internal dynamics is an essential ingredient or a secondary effect. In the language of the Dimensional Weight Operator (Section 24.4), this internal dynamics may be tentatively associated with the degree of freedom $\pi^{(6)}$ (soliton radius), which would thereby acquire a dynamic interpretation beyond its static geometric extent — a reinterpretation that remains speculative, is not used in deriving any numerical result in this paper, and applies to this one degree of freedom only.

25.8 Relation Between the Energetic and Topological Arguments

The present section advances two complementary conditions that together single out $K_{WC} = 10$: (i) an **energetic** condition based on the r^5/r^3 scaling disparity, which creates a deep potential well for intermediate wave-centre counts (Section 15.1); and (ii) a **topological** condition requiring an integer winding number Q on S^2 (Section 19.4). These are not independent post-hoc justifications of the same number; they are mutually reinforcing constraints. The r^5/r^3 argument explains why K_{WC} cannot be too small (shallow well) or too large (volumetric overload), while the topological argument explains why, within the allowed range, only discrete integer values are permitted. The specific value $K_{WC} = 10$ emerges as the unique integer that simultaneously satisfies both constraints under the octahedral symmetry of the $Im\bar{3}m$ BCC lattice. A rigorous proof that no other integer passes both filters remains a task for the OpenWave M4 simulation.

25.9 Summary

- The general soliton wave equation is $(\partial_t^2 - c^2 \nabla^2) \Psi + \mathcal{F}(\Psi) = 0$.
- The coupling coefficient is fixed by BCC geometry: $\gamma = 1/\epsilon_M = N_{\text{final}} \pi^3 \approx 2.41 \times 10^4$. Two variants are available: γ_{final} (anchored to α) and $\gamma_{\text{geo}} = 8\pi^7$ (ideal BCC limit); the 0.058% difference may be critical for K-selectivity.
- Three complementary forms for $\mathcal{F}$ are proposed:
 - Variant A: $\gamma \Psi^3$ (pure cubic, minimal implementation);
 - Variant B: $\gamma(1 - \rho/\rho_0) \Psi^3$ (density-modulated, links stability to the EMC push-out deficit);
 - Variant C: $\gamma \|\Psi\|^2 \Psi$ with an explicit 1-3-6 source operator $\mathbf{J}_{1-3-6}(\mathbf{r}, t)$ (directly encodes the discrete wave-centre architecture of the electron).
- The Degraded EMC Wall is proposed to provide the necessary boundary condition for the nonlinearity: its radius, estimated as $r_{\text{wall}} \sim r_e/\alpha$, is consistent with the Compton wavelength and may ensure a broad adiabatic transition zone ($\sim 137 r_e$) in which the density-modulated term can act without sharp gradients. A possible density peak within the wall would further assist stabilisation by creating a local defocusing barrier.
- The winding number $Q = 10$ on S^2 is proposed as the topological selection rule that would isolate the electron ground state under $Im\bar{3}m$ constraints; rigorous proof that $Q = 10$ is energetically preferred over other integers remains a task for the OpenWave M4 simulation.
- The 1-3-6 partition is the unique self-consistent candidate that simultaneously satisfies the topological winding, the cubic nonlinearity, and the octahedral symmetry of the BCC lattice; its stability is a postulate pending numerical verification.
- The energetic (r^5/r^3) and topological arguments are complementary: the former restricts the range of allowed K_{WC} , the latter restricts K_{WC} to integer values; together they single out $K_{WC} = 10$ as the only candidate satisfying both constraints.
- The coupling $\gamma \approx 8\pi^7$ (in its geometric limit) directly expresses the 7-dimensional charged-weak budget of the BCC lattice.
- The model is well-posed and falsifiable; the stability of the 1-3-6 configuration is a postulate whose numerical verification is the immediate objective of the OpenWave M4 simulation.

26 Predictive Power

The EWT model yields several precise, quantitative predictions that follow directly from the geometry of the Soliton and the BCC lattice. The results summarized in Table 20 demonstrate the internal consistency of the zero-calibration framework.

Table 20: Principal Geometric Predictions of the EWT Framework

Physical Quantity	Geometric Prediction	Target	Relative Error
G_{geom}	$6.6775199755 \times 10^{-11}$	6.674305×10^{-11}	0.048169%
$\alpha_{\text{geom}}^{-1}$	137.036262364	137.035999084	0.000192%
a_e^{EWT}	1159.916228 ppm	1159.652182 ppm	0.022769%
a_μ^{EWT}	1166.212608 ppm	1165.920610 ppm	0.025044%
a_τ^{EWT}	1176.838130 ppm	1177.210000 ppm	0.031589%

Note: Values for a_e , a_μ , and a_τ are full anomalous magnetic moments. All predictions are obtained from the geometric Python implementation described in the Appendix. Error for a_τ is compared with SM prediction.

26.1 Prediction of the Fundamental Value of G

The model predicts the value of G as a direct function of microscopic geometric parameters through the operator $\mathcal{U}$ (Section 11.5). For the zero-calibration inputs used in this work, the geometric identity gives

$$G_{\text{geom}} \approx 6.6775199755 \times 10^{-11} \text{ m}^3 \text{ kg}^{-1} \text{ s}^{-2}. \quad (269)$$

Precise experimental measurements of G (e.g., torsion balance, atom interferometry) directly test this prediction.

26.2 Predictions for Lepton Properties: The First-Principles AMM Predictions

The full anomalous magnetic moments of the entire lepton family are computed from the same BCC lattice geometry that governs G and α_{geom} . The results form a compact monotonic sequence:

$$\boxed{a_e^{\text{EWT}} = 1.159916 \times 10^{-3}} \quad \boxed{a_\mu^{\text{EWT}} = 1.166213 \times 10^{-3}} \quad \boxed{a_\tau^{\text{EWT}} = 1.176838 \times 10^{-3}} \quad (270)$$

with relative errors 0.022769%, 0.025044%, and 0.031589%.

The projection rules $\mathcal{O}_e = \mathcal{O}_\tau = 1$ and $\mathcal{O}_\mu = 1/(4\pi^2)$ are fixed by the dimensional hierarchy and contain no generation-specific parameters. A fourth generation would require a second 2D projection and is geometrically forbidden by the saturation limit of the BCC lattice.

26.3 Magnetic Sensitivity $G(B)$ and Hypotheses Testing

The model predicts a dependence of the effective gravitational coupling on local magnetic coherence, as described in Section 18. In the zero-calibration formulation, the push-out operator

3222 is expressed through the geometric stiffness:

$$\mathbf{T}_{\text{II}} = \left(\frac{1}{A_\pi \cdot N_{\text{geom}}} \right)^3. \quad (271)$$

3223 The observable shift is expected to be small in ordinary environments:

$$\left(\frac{\Delta G}{G} \right)_{\text{obs}} = \xi(B) \cdot \mathbf{T}_{\text{II}}, \quad (272)$$

3224 where $\xi(B)$ is the coupling efficiency of the local magnetic field to the soliton's geometry. The
3225 sign of the effect distinguishes the hypotheses of Section 18.4.

3226 26.4 AMM as a Strong Test of Geometric Universality

3227 Because AMM measurements are exceptionally precise, they provide an ideal testing ground for
3228 the geometric mechanism. A single universal modulator ϵ_M , together with the recursive nodal
3229 structure, replaces the perturbative loop corrections of the Standard Model.

3230 26.5 Correlations with Neutrino Flux

3231 Since G emerges from the effective density $N_{\nu, \text{eff}}$, the model allows minute correlations between
3232 measured G and local neutrino flux densities. High neutrino flux may momentarily alter the
3233 local EMC background, leading to sub-ppm modulations of G .

3234 26.6 Spectral and Geometric Modal Tests

3235 The modal nature of the π^3 factor implies that internal geometric excitations may leave traces
3236 in the frequency spectrum of small fluctuations of G . The model predicts characteristic nodal
3237 frequencies of the soliton's standing modes.

3238 26.7 Tests using Gravitational Wave Observations

3239 If G is emergent from the BCC lattice, gravitational waves may exhibit small dispersion effects:

$$v_{\text{GW}} \simeq c(1 - \delta_{\text{dispersion}}), \quad (273)$$

3240 where $\delta_{\text{dispersion}}$ depends on the local nodal density. Arrival-time comparisons between GW and
3241 electromagnetic signals constrain this effect.

3242 26.8 Test on Bose-Einstein Condensates

3243 A BEC state synchronises the local magnetic coherence across a macroscopic volume. The model
3244 predicts a shift

$$G_{\text{eff}}^{(\text{BEC})} = G(1 + \delta_{\text{BEC}}), \quad \delta_{\text{BEC}} \propto \mathbf{T}_{\text{II}}. \quad (274)$$

3245 Consistent with the push-out mechanism, the primary prediction is $G_{\text{eff}} > G$. Atom interferom-
3246 etry on ultra-cold clouds before and after BEC formation can test this directly.

26.9 The Higgs Soliton vs. Fundamental Scalar Field

The EWT model identifies the Higgs as a resonant state ($K_{WC} = 117$) rather than a fundamental scalar field. This leads to specific predictions for Higgs-vector mixing:

$$\sin^2 \theta_{ZH} \approx 0.4686, \quad \sin^2 \theta_{WH} \approx 0.5906. \quad (275)$$

Angular asymmetries or interference patterns in Higgs decays at HL-LHC or FCC that match these geometric values would falsify the VEV mechanism of the Standard Model.

27 Falsifiability and Model Constraints

The following outcomes represent critical tests that can either **falsify** the core tenets of the EWT model or place stringent constraints on specific parameters and hypotheses. These tests are focused on the **existence or non-existence** of predicted effects, independent of the sign of the dynamic coupling (Hypotheses 1 and 2).

- **Falsification of Fundamental Constants (G):** Precise measurements of G consistently rejecting G_{model} (Eq. 26.1) beyond the level of uncertainty while maintaining the assumed values of microscopic parameters.
- **Falsification of Dynamic Coupling ($G(B)$):** The observation of a null effect, i.e., the absence of any observed $G(B)$ dependence above the detection threshold, assuming the technical feasibility of such a test. This outcome would support **Hypothesis 3 (No Influence)** and refute the core idea of magneto-geometric coupling.
- **Falsification of Correlations:** The absence of statistical correlations between fluctuations in G and external factors (neutrino flux, magnetic fields) within the range predicted by the model (ref. Section 26.5).
- **Falsification of Full Lepton AMM Predictions (a_e, a_μ, a_τ):** Future high-precision measurements of the electron, and muon, anomalous magnetic moments that deviate significantly from the full AMM predictions $a_e^{\text{EWT}} = 1.159916 \times 10^{-3}$, $a_\mu^{\text{EWT}} = 1.166213 \times 10^{-3}$, and $a_\tau^{\text{EWT}} = 1.176838 \times 10^{-3}$ (Table 9) would falsify the model in its present formulation. For the tau, the current reference value is the Standard Model prediction $a_\tau^{\text{SM}} = 1.177210 \times 10^{-3}$, not a direct measurement. Therefore the tau comparison is a consistency test against the SM prediction, not a direct experimental falsification. The projection rules underlying these predictions are completely determined by the dimensional hierarchy of the Geometric Ladder: $\mathcal{O}_e = 1$ (3D core), $\mathcal{O}_\mu = 1/(4\pi^2)$ (2D planar shell), and $\mathcal{O}_\tau = 1$ (3D volumetric shell). A significant deviation of any of the three measured anomalies from the predicted values would therefore directly challenge the geometric core of the model. The compact monotonic sequence of prediction errors— $0.022769\% \rightarrow 0.025044\% \rightarrow 0.031589\%$ —provides a stringent, correlated test: any future measurement that breaks this monotonicity would also indicate a structural tension with the BCC lattice framework.

27.1 Practical Considerations and Detection Limits

In practice, the expected magnitude of the relative change $\Delta G/G$ is governed by the robustness of the dynamic geometric equilibrium between energy scaling (r^5) and volumetric displacement (r^3). Due to this compensatory mechanism, the predicted deviations in near-equilibrium (low-field) environments are expected to be extremely subtle, likely requiring a detection sensitivity in the range of 10^{-9} to 10^{-12} .

While these requirements are stringent, they align precisely with the current state-of-the-art in quantum metrology and atom interferometry. Modern platforms, such as MAGIS-100 or advanced gravity gradiometers, are specifically designed to operate within these detection limits to probe dark matter and gravitational waves.

The model further posits that the detection threshold is fundamentally tied to the **magnetic flux density** or **quantum coherence level** of the source. In extreme high-field regimes or coherent macroscopic states (such as BEC), the compensatory mechanism is hypothesized to reach its non-linear limit, potentially shifting the magnitude of $\Delta G/G$ towards the 10^{-7} range. Consequently, even a null result within current experimental sensitivities would provide critical boundary values for the volumetric "stiffness" of the EMC medium governed by $\mathbf{T}_{\text{II}}$ and the saturation point of the geometric equilibrium. This ensures that the framework remains fully falsifiable, providing a clear mapping for the transition from the "low-field artefact" of invariant G to the dynamic G_{eff} regime predicted by EWT.

27.2 Two Readings of the Higgs Sector: What a Future Measurement Can Settle

The Higgs-sector tests proposed in Section 3.4 rest on a specific question: which of two readings of the Higgs sector is correct. The two readings make different commitments about the nature of the Standard Model, and stating those commitments explicitly clarifies what the proposed measurements can and cannot settle.

The three Standard-Model theses

The interpretation of the electroweak sector commonly presented as the Standard Model rests on three theses about the Higgs:

1. **The Higgs field is fundamental.** A scalar $SU(2)$ doublet Φ with hypercharge $1/2$ transforms under the gauge group as a matter field and carries no substructure at any energy scale.
2. **The vacuum expectation value is a fundamental constant.** The value $v = (\sqrt{2} G_F)^{-1/2} \approx 246$ GeV is a property of the vacuum of the underlying theory, fixed by the parameters of the Lagrangian and the renormalisation condition.
3. **The Higgs mechanism is the fundamental source of mass.** The masses of the W and Z bosons and of the charged leptons arise from the coupling of those fields to Φ . No deeper mechanism contributes to the values of those masses at any order.

The electroweak Lagrangian, understood as a quantum field theory, is one formal realisation of these theses. The theses are not logically equivalent to the formalism. Each can be denied while the formalism continues to describe the same low-energy physics, at least as an effective field theory.

What Energy Wave Theory claims instead

The model presented in this work replaces the three theses as follows:

1. The Higgs boson is a composite soliton of the BCC lattice with wave-centre count $K_{WC} = 117$. The field Φ is the low-energy projection of the collective degrees of freedom of that soliton, not a fundamental object.

- 3327 2. The value $v \approx 246$ GeV is emergent from the same lattice geometry that determines α , the
3328 lepton anomalous magnetic moments, and the gravitational coupling G . It is not a free
3329 parameter of the vacuum.
- 3330 3. The masses of the W and Z bosons and of the charged leptons are derived from the
3331 geometric parameters of the soliton states (the wave-centre count). The Higgs mechanism
3332 is not required to generate these masses.

3333 What the proposed measurements can settle

3334 The two readings coincide at the level of the tree-level HZZ and HWW couplings, under the
3335 restricted hypothesis of Eq. (37). They differ in the presence or absence of internal structure at a
3336 characteristic length scale, which manifests as a momentum-dependent deformation of the HZZ
3337 vertex at energies comparable to the inverse of that scale. The explicit form of the deformation
3338 is not derived in this work; it awaits the soliton form factor calculation.

3339 The observables proposed in Section 3.4 test precisely this difference. Pillar I is a null test
3340 on the absolute ZH production rate: a statistically significant deviation from Eq. (38), after the
3341 specified corrections, falsifies the restricted hypothesis. Pillar II is a search for a momentum-
3342 dependent or tensorial deformation of the HZZ vertex in the Legendre moments of the Z pro-
3343 duction angle. Two outcomes are possible:

- 3344 • **The Standard-Model theses hold.** A null result on the angular moments, at a precision
3345 sufficient to exclude any deformation of the magnitude that a composite soliton of the
3346 known internal size would produce, confirms the three theses at the tested scale. It leaves
3347 the Energy Wave Theory reading constrained but not excluded, since the EWT angular
3348 prediction is not currently quantified.
- 3349 • **The Standard-Model theses fail.** A statistically significant deformation of the angular
3350 moments, consistent with a soliton-derived form factor, falsifies the three theses at the
3351 tested scale. It does not falsify the Standard Model as an effective field theory: the elec-
3352 troweak sector continues to describe physics below the compositeness scale, with the soliton
3353 replacing the scalar field at higher energies. What is falsified is the interpretation of the
3354 electroweak Lagrangian as a fundamental description of nature.

3355 The distinction between falsifying the Lagrangian and falsifying its interpretation is central to
3356 the logic of this subsection. The Standard Model has been reinterpreted many times in response
3357 to new observations, from the discovery of the muon to the discovery of neutrino masses. The
3358 three theses above are the current interpretation of the Higgs sector. If they are wrong, the
3359 correct response is a reinterpretation, not a discarding of the framework. This is what the
3360 Energy Wave Theory proposes, and the measurements proposed in Section 3.4 are the way to
3361 decide between the two readings.

3362 28 Robustness Analysis: Geometric Stability and Sensitiv- 3363 ity

3364 To demonstrate that the Enhanced EWT model is not a result of numerical coincidence, a
3365 series of sensitivity tests were performed. This analysis examines how small perturbations in the
3366 fundamental geometric inputs affect the physical outputs. By isolating each primary variable,
3367 the structural rigidity of the vacuum lattice is verified against experimental CODATA/PDG
3368 benchmarks.

28.1 Robustness Analysis of the Neutrino Soliton Radius and Geometric Identity

The structural integrity of the EWT framework is evaluated through the stability of the fundamental identity

$$\Delta N_\nu \sim \frac{1}{\epsilon_G}. \quad (276)$$

where ϵ_G is the gravitational deficit associated with the reference soliton. This equivalence suggests that the statutory constituent count, derived from the ratio of the neutrino radius to the Planck scale, must inherently align with the geometric deficit required to scale gravity from its classical base G_{Base} to the observed value.

To verify the absence of numerical fine-tuning, a sensitivity analysis was conducted by applying relative perturbations of $\pm 20\%$ to the primary geometric inputs: the statutory neutrino radius r_ν and the fundamental EMC spacing λ_l . The resulting compliance curves are shown in Fig. 8. They demonstrate that even under significant variations in the input scales, the compliance ratios remain strictly within the $\pm 30\%$ tolerance boundaries.

Figure 8: **Structural Robustness Analysis of the Statutory Density $N_{\nu,\text{stat}}$** . The plot tracks the stability of the statutory background population $N_{\nu,\text{stat}}$ against relative fluctuations in the neutrino radius r_ν and the EMC spacing λ_l . Both curves remain within the established $\pm 30\%$ compliance boundaries (0.7 to 1.3 ratio). This stability ensures that the geometric vacuum parameters do not require fine-tuning.

This performance confirms that the EWT model is not a product of precise numerical coincidence, but is instead rooted in a robust geometric power-law relationship.

28.2 Gravitational Surface Transition and $N_{\nu,\text{eff}}$

The robustness test focuses on the relationship between the geometric volume deficit and the emergent gravitational constant G . As detailed in Section 11.10, gravity is interpreted as a surface effect resulting from a three-dimensional packing deficit within the EMC medium.

Figure 9: Analysis of the G-constant surface transition. The green curve illustrates the evolution of G as a function of the effective volume deficit N_{ν} . The red intersection point marks the deterministic alignment with G_{CODATA} at the calculated $N_{\nu,\text{eff}}$.

The results illustrated in Fig. 9 confirm the following physical constraints:

- **Transition trajectory:** The evolution of the curve follows the $G \propto N_{\nu}^{-1/2}$ scaling law. This confirms the gravitational interaction as a surface manifestation of the internal volumetric dilution.
- **Deterministic convergence:** The intersection with the G_{CODATA} threshold justifies the transition to the effective volume deficit

$$N_{\nu,\text{eff}} \approx 6.2472 \times 10^{48}, \quad (277)$$

obtained from the geometric dilution factor X_{eff} .

- **Model rigidity:** The steep slope of the transition curve indicates that the system is highly sensitive to the internal geometry. A deviation of even 1% in the value of N_{ν} results in a significant departure from G , proving that the EWT unification is not a result of arbitrary curve-fitting.

28.3 Sensitivity of α^{-1} to the Geometric Modulator N_{geom}

This test evaluates the stability of the fine-structure constant derivation by examining the influence of the dimensionless geometric stiffness N_{geom} . In the EWT framework, $\alpha_{\text{geom}}^{-1}$ is determined by the fixed vacuum geometry A_π modulated by the magnetic deficit $\epsilon_M = 1/(N_{\text{geom}}\pi^3)$.

Figure 10: Sensitivity analysis of the inverse fine-structure constant. The plot illustrates the convergence of the model toward the CODATA value as a function of the geometric stiffness coefficient N_{geom} .

The analysis of the results presented in Fig. 10 confirms:

- **Geometric necessity:** Precise alignment with $\alpha_{\text{CODATA}}^{-1}$ occurs only when the complete stability factor is applied. The “golden point” intersection at

$$N_{\text{geom}} \approx 778.8025 \quad (278)$$

proves that the fine-structure constant emerges from a rigid geometric base corrected by a finite magnetic deficit.

- **Force hierarchy indication:** While the modulator ϵ_M is shared by both G and α^{-1} , the gravitational constant operates on a significantly different scale through the cubic factor $(\epsilon_M/A_\pi)^3$ and the surface projection $N_{\nu, \text{eff}}^{-1/2}$.

28.4 Phase Space Analysis: EWT Trajectory vs Standard Model Interpretation

The phase-space mapping between the inverse fine-structure constant α^{-1} and the electron anomalous magnetic moment a_e reveals a fundamental geometric trajectory. By varying the

vacuum stiffness parameter N , the model demonstrates that α^{-1} and a_e are not independent constants, but emergent properties of the same underlying geometric modulator.

Figure 11: Phase space correlation between the inverse fine-structure constant and the electron anomalous magnetic moment. The curve represents the EWT geometric trajectory, showing that α^{-1} and a_e emerge from the same vacuum stiffness.

The experimental CODATA point lies close to this EWT trajectory, as shown in Fig. 11, with a residual offset of approximately 0.022769%. In the EWT framework, this offset is not interpreted as model failure, but as a consequence of the structural difference between the geometric vacuum picture and the point-like renormalisation programme of the Standard Model.

28.5 Parametric Unification: The Stability Path of G and α

A parametric analysis of the relationship between G and α^{-1} was performed by varying the geometric modulator N . The resulting trajectory, derived from the geometric operator $\mathcal{U}$, shows that α^{-1} remains tightly constrained by the core geometry A_π , whereas G is significantly more sensitive to changes in the stiffness parameter.

The resulting trajectory is shown in Fig. 12. This sensitivity difference follows directly from the algebraic structure:

$$\alpha_{\text{geom}}^{-1} \sim A_\pi - \frac{1}{N\pi^3}, \quad G_{\text{geom}} \sim \frac{1}{N^3 \sqrt{N_{\nu, \text{eff}}}}. \quad (279)$$

Thus, small changes in N affect G much more strongly than α . This explains why the electromagnetic sector appears stable while the gravitational sector is more sensitive to microscopic geometric parameters.

Figure 12: The EWT Unification Path. The magenta line represents the geometric correlation between gravity and electromagnetism as a function of the vacuum stiffness parameter N .

28.6 EWT Unification: Convergence of G and a_e on the Vacuum Stiffness Isentrope

A fundamental consistency check is the interdependence between G and a_e at a single geometric stiffness value

$$N_{\text{geom}} \approx 778.8025. \quad (280)$$

At this point, G_{geom} and a_e^{EWT} are both determined from the same BCC lattice parameters, as illustrated in Fig. 13. This is not a fit: the value of N_{geom} is fixed by the packing geometry and the impedance ζ .

28.7 Robustness Analysis: Geometric Stability and Vacuum Elasticity

To evaluate the reliability of the derived gravitational constant, a sensitivity analysis of the coupling between the soliton volume and the vacuum stiffness was performed. The structural stability is governed by the relationship

$$N \propto N_{\nu, \text{eff}}^{-1/6}, \quad (281)$$

which follows from the volumetric scaling $N_\nu \propto r^3$ and the stiffness-radius relation $N \propto r^{-1/2}$.

The resulting stability relationship is illustrated in Fig. 14. This damping factor protects the geometric vacuum parameters from large fluctuations of the EMC density. In the current model, the relevant stiffness is N_{geom} , not an arbitrary fitted value.

Figure 13: EWT Unification: Direct convergence of the gravitational constant G and the electron anomaly a_e at the geometric stiffness N_{geom} .

28.8 Structural Robustness and Resonance Stability of the Lepton Hierarchy

The same geometric stiffness N_{geom} anchors the recursive lepton hierarchy. The sensitivity gradients of a_μ and a_τ are shown in Fig. 15. They differ because the muon is a 2D surface resonance, while the tau is a 3D volumetric resonance. This is consistent with the dimensional hierarchy established in Section 3.

28.9 Electroweak and CKM Coincidence: Geometric Robustness of $\sin^2 \theta_W$ and $\sin \theta_C$

The electroweak and Cabibbo mixing sectors converge at the same geometric anchor N_{geom} , as shown in Fig. 16. The π^6 bosonic coupling is steeper than the π^5 fermionic coupling, reflecting the difference between volumetric and surface resonances.

The Cabibbo sector remains sensitive to the quality of the quark mass inputs. When PDG experimental quark masses are used, the geometric mixing operator C_{fermion} reproduces $\sin \theta_C$ to within 0.0055%. The remaining discrepancy with EWT-derived quark masses originates from the mass prediction sector, not from the mixing geometry itself.

28.10 Lock-In Test: Independent Determination of N_{geom}

The robustness analysis presented so far demonstrates that the model is stable under perturbations of its inputs. A complementary and more stringent test concerns whether the geometric

Figure 14: Gravity Stability Equilibrium: The $r^{-1/2}$ trajectory of nodal stiffness N relative to the cubic scaling of soliton volume N_ν .

stiffness N_{geom} is *over-determined* by independent physical sectors, or merely fitted to a single observable. The results of such a test are reported below.

28.10.1 Method

For each of seven physical sectors — α^{-1} , G , a_e , a_μ , a_τ , $\sin^2 \theta_W$, and $\sin \theta_C$ — the following quantities are computed:

1. the value of the sector at $N_{\text{geom}} = 778.8025$;
2. the *drift* of that value when N is changed by ± 10 ;
3. the logarithmic derivative $\beta = d \ln O / d \ln N$ at N_{geom} , obtained by central difference in $\log N$ with step 10^{-6} ;
4. the *resolution*, defined as the relative error of the sector at N_{geom} divided by $|\beta|$, which measures how narrowly the sector can locate N ;
5. the *optimal* value N_{opt} for each sector, found by log-space scan followed by bisection.

The procedure is implemented in the OpenWave script `m4_11_lock_in_n_scan.py` [54].

The sectors are classified into three groups according to their resolution:

- **PRIMARY** — resolution $< 1\%$. These sectors can independently locate N at the sub-percent level.

Figure 15: Stability Analysis of the Lepton Hierarchy: Normalized response of a_μ and a_τ to geometric perturbations.

- **WEAK** — resolution between 1% and 100%. These sectors are consistent with N_{geom} but cannot discriminate it from neighbouring values.
- **NO CONSTRAINT** — resolution $> 100\%$. These sectors provide no information about N .

28.10.2 Results

The resolution analysis is summarised in Table 21. The grouping of sectors follows directly from the resolution column.

28.10.3 PRIMARY sectors: G , a_τ , and $\sin \theta_C$

Three sectors resolve N at the sub-percent level. The two strongest are the gravitational constant G (0.004%) and the tau anomalous magnetic moment a_τ (0.14%). Their separately optimal values are

$$N_{\text{opt}}(G) = 778.83, \quad N_{\text{opt}}(a_\tau) = 779.92, \quad (282)$$

which agree to within

$$\Delta = 0.14\% \text{ of } N_{\text{geom}}. \quad (283)$$

Crucially, the two sectors are constructed from completely different chains. G arises from the gravitational self-consistent derivation involving λ_l , $N_{\nu, \text{eff}}$, and the surface projection. a_τ arises from the recursive lepton shell damping governed by ϵ_M and the Fibonacci latching. Neither chain uses the other's inputs. The agreement between them is therefore not tautological.

Figure 16: Shift-Normalized Robustness Analysis: The intersection of the $\sin^2 \theta_W$ and $\sin \theta_C$ trajectories at the geometric lock-in point N_{geom} .

Table 21: Resolution of N_{geom} by independent physical sectors. The three groups are separated by horizontal rules.

Sector	$\beta = d \ln O / d \ln N$	Resolution	N_{opt}
<i>PRIMARY (resolves N, < 1%)</i>			
G	-12.000002	4.0×10^{-5}	778.83
a_τ	+0.220297	1.4×10^{-3}	779.92
$\sin \theta_C$	-0.008921	6.2×10^{-3}	774.03
<i>WEAK (consistent, 1%-100%)</i>			
$\sin^2 \theta_W$	-0.045754	1.5×10^{-1}	910.04
a_e	+0.001285	1.8×10^{-1}	661.63
a_μ	+0.001415	1.8×10^{-1}	661.69
<i>NO CONSTRAINT (> 100%)</i>			
α^{-1}	+3.0 $\times 10^{-7}$	6.4×10^0	105.85

The exponent $\beta_G = -12$ (rather than the naive -3) is a structural consequence of the self-consistent derivation of λ_l : the lattice spacing scales as $\lambda_l \propto N^{-6}$, and G inherits an additional N^{-9} dependence through $N_{\nu, \text{eff}}$, compounding with the explicit N^{-3} factor. This makes gravity by far the most sensitive probe of the lattice stiffness.

The Cabibbo angle $\sin \theta_C$ formally lands in the PRIMARY group with a resolution of 0.62%. This result is, however, conditioned on the central PDG values for the light quark masses. The

experimental uncertainty on m_d and m_s spans approximately 14%, roughly fifteen times larger than the geometric correction being tested. At the low corner of that range no positive N reproduces $\sin\theta_C$. The Cabibbo leg is therefore treated as *conditionally* primary, not as a fully independent constraint.

28.10.4 WEAK sectors: a_e , a_μ , and $\sin^2\theta_W$

Three sectors are consistent with N_{geom} but cannot discriminate it from neighbouring values. Their resolutions of approximately 15–18% reflect different suppression mechanisms.

For the electron anomalous magnetic moment a_e , the sensitivity to N is suppressed because the prediction is dominated by the nearly N -independent Schwinger term. The electron AMM therefore confirms the overall framework but does not constrain the lattice stiffness.

For the muon anomalous magnetic moment a_μ , the projection operator $\mathcal{O}_\mu = 1/(4\pi^2)$ suppresses the sensitivity of the muon shell. The muon leg is consistent with N_{geom} but, like the electron, cannot discriminate between neighbouring values.

For the Weinberg angle $\sin^2\theta_W$, the logarithmic derivative is small ($\beta \approx -0.046$), giving a resolution of 14.6%. The comparison between the model value $\sin^2\theta_W = 0.23276$ and the PDG reference uses the $\overline{\text{MS}}$ scheme, while the on-shell value derived from the PDG masses is 0.22305. The geometric correction C_{gap} occupies the same slot as a known scheme-conversion factor of approximately 1.06%. Consequently, the Weinberg leg cannot yet carry independent weight.

28.10.5 NO CONSTRAINT: α^{-1}

The inverse fine-structure constant provides no constraint on N . Its logarithmic derivative is $\beta \approx 3 \times 10^{-7}$, giving a resolution of 635%. This is expected and consistent with the model structure: α^{-1} is dominated by the geometric core A_π , and the ϵ_M correction is tiny. α therefore confirms the model but does not constrain its central parameter. Its inclusion in the lock-in analysis serves as a consistency check: the absence of a constraint is itself a prediction of the model's structure.

28.10.6 Interpretation

The lock-in test demonstrates that N_{geom} is not a fitted parameter in the usual sense. It is a *node* at which two independent physical sectors — gravity and the tau anomalous magnetic moment — converge to within 0.14%, with completely different construction chains and different sensitivities to the lattice stiffness.

The PRIMARY sectors are those whose prediction chains contain N at high powers ($\beta_G = -12$, $\beta_{a_\tau} = 0.22$) and whose targets are known with sufficient precision. The WEAK sectors are those whose sensitivity is suppressed by projection operators or by dominant N -independent terms. The NO CONSTRAINT sector is dominated by the geometric core A_π and is essentially insensitive to N .

This hierarchy is a falsifiable structural feature of the model. If future measurements of a_τ (currently only bounded experimentally) or of G (currently known to 2.2×10^{-5}) were to shift either sector's optimal N beyond the common interval, the model would be challenged. If, on the other hand, the PRIMARY sectors were to remain in agreement while a WEAK sector moved into the PRIMARY group, the model would be strengthened by the addition of a third independent constraint.

29 Geometric Phase Transitions: From Neutrino to Black Hole with EMC Wall

In the EWT framework, the vacuum lattice is a physical medium with a finite redistribution capacity. The formation of a **Geometric Black Hole (GBH)** represents a phase transition where the vacuum is pushed to its absolute elastic and geometric limits.

29.1 Hierarchy of Vacuum States and the G-Operating Point

The hierarchy of states is governed by the depth of the density deficit relative to the statutory equilibrium:

- **Effective Point** ($N_{\nu,\text{eff}} \approx 6.25 \times 10^{48}$): The standard operating point of attractive gravity (approx. 99.98% deficit relative to background).
- **Statutory Limit** ($N_{\nu,\text{stat}} \approx 3.30 \times 10^{52}$): The saturation ceiling where gravity inverts into repulsion (**EMC Wall**).
- **Max Packing** ($N_{\nu,\text{max}} \approx 5.30 \times 10^{54}$): The asymptotic structural limit of the BCC lattice at the Planck scale.

The GBH Core: Finite Vacuum Exhaustion and Pure Wave Centers

Unlike General Relativity, EWT defines the interior of a GBH as a domain of **maximal individual energy concentration** (ρ_E) and **maximal medium deficit** (ρ). This state is realized by high-energy neutrino solitons acting as pure Wave Centers (WC).

Empirical Validation (Supernovae): The observation that **99% of supernova energy is released as neutrinos** constitutes empirical confirmation that the collapse of matter under extreme gravity leads to the conversion of the dominant mass into the **minimal geometric state** of the Neutrino (r_ν) at the point d_{crit} . This fact justifies the adoption of the Neutrino as the fundamental WC for the GBH model.

The EMC Wall and the Push-Out Mechanism

The EMC Wall is a physical density barrier in a vacuum created when the medium (BCC network) cannot keep up with the redistribution of displaced components (EMC). In ordinary solitons (such as leptons) this barrier exists in a **degraded** form – the *Degraded EMC Wall* discussed in Sec. 11.11 – where the local EMC density exceeds the statutory background $N_{\nu,\text{stat}}$ only moderately, and the wall acts as a passive geometric low-pass filter. In a Geometric Black Hole (GBH), however, the push-out mechanism is driven to its extreme: the core exhausts the vacuum so severely that the accumulated EMC density at the wall **significantly exceeds** the statutory background $N_{\nu,\text{stat}}$, turning the wall into an insurmountable barrier. The EMC wall then defines the geometric event horizon of the black hole. The relationship between the black hole core's energy and the wall's density is defined by the displacement flux:

$$\Delta\rho_{E(\text{core})} \xrightarrow{\text{push-out}} \Delta\rho_{(\text{wall})} \geq N_{\nu,\text{stat}} \quad (284)$$

Energy Dissipation and Degradation

Energy exchange between the Geometric Black Hole and the external environment remains possible; however, the emitted energy must adopt a **degraded form**. The EMC Wall acts as a

35 81 mandatory transducer, where the extreme resistance of the saturated lattice forces all outgoing
35 82 flux into states compatible with the medium's localized stiffness.

35 83 **Astrophysical Jets and the Density Wall**

35 84 The maximal vacuum exhaustion within the GBH core necessitates a **massive reciprocal ac-**
35 85 **cumulation** of EMCs at the event horizon's boundary—the **EMC Density Wall**. This wall
35 86 possesses extreme nodal stiffness, anchoring ultra-strong magnetic fields. Astrophysical jets act
35 87 as **structural discharge mechanisms**, where the immense potential of the compressed lattice
35 88 is released along the axes of least resistance (the poles).

35 89 **The EMC Barrier and Orbital Stability**

35 90 Beyond the **Statutory Limit** ($N_{\nu, \text{stat}}$), the density gradient undergoes a sign reversal ($\nabla \rho > 0$).
35 91 This creates a localized **Repulsion Zone** (anti-gravity). The event horizon thus functions as a
35 92 buffer; matter is either stabilized by this "gravitational conjunction" or **actively ejected** into
35 93 jets upon encountering the super-statutory pressure of the wall.

35 94 **The EMC Wall: Selective Frequency Response**

35 95 The extreme nodal stiffness of the **EMC Wall** (approaching $N_{\nu, \text{max}}$) establishes a **high-pass**
35 96 **filter**. Because the lattice bonds in the wall are pushed to their elastic limit, only waves with **ex-**
35 97 **trremely high frequencies** (Gamma and X-rays) have the energy density required to overcome
35 98 the medium's inertia.

35 99 **The EMC Wall: Decomposition of Matter**

36 00 As leptonic matter approaches the boundary, the transition on the wall's congestion creates an
36 01 insurmountable **impedance mismatch**. The vacuum lattice becomes too rigid to maintain the
36 02 wave structure of leptons, leading to the **structural breakdown** of the particle soliton.

36 03 **Hypothesis: Gravitational Waves as Background Density Shifts**

36 04 Within the EWT framework, gravitational waves can be interpreted as propagating pulses that
36 05 momentarily increase the **statutory background density** ($N_{\nu, \text{stat}}$) of the BCC lattice. Cru-
36 06 cially, the soliton's internal push-out mechanism is blocking EMCs; the matter does not absorb
36 07 additional EMCs. Instead, the passing wave momentarily elevates the surrounding medium's
36 08 density toward the EMC Wall threshold. As the background density $N_{\nu, \text{stat}}$ surges, the relative
36 09 gradient between the soliton's core (the vacuum exhaustion zone) and the statutory environment
36 10 is altered. This transient shift in the background reference point modulates the Ω_{Push} operator,
36 11 manifesting as a temporary change in the "gravitational shadow". Once the peak of the back-
36 12 ground EMC pulse passes, the lattice undergoes relaxation, restoring the statutory equilibrium.
36 13 This interpretation suggests that gravitational waves are not a change in matter itself, but a
36 14 moving "impedance spike" in the vacuum background that matter inhabits.

36 15 In this scenario, the matter "does not notice" the wave because its internal structural iden-
36 16 tity is preserved relative to the shifting background. The wave is only detectable via phase-
36 17 sensitive measurements (interferometry), where the transient change in lattice impedance affects
36 18 the propagation velocity of massless wave packets (photons) without disrupting the integrity of
36 19 the leptonic solitons.

Hypothesis: Stellar Stability and Local EMC Saturation

In the context of stellar evolution, the EWT framework suggests that the equilibrium of a star is not solely a result of thermodynamic radiation pressure, but rather a consequence of the **structural impedance of the vacuum**. As stellar mass accumulates, the central region approaches a state of extreme vacuum exhaustion, while the surrounding layers may experience a density surge toward the **EMC Wall threshold** ($N_{\nu,\text{tmp}} \rightarrow N_{\nu,\text{stat}}$). This creates a "mechanical cushion" of high nodal density that effectively supports the matter against gravitational collapse. In this scenario, the stellar plasma "floats" on a layer of saturated lattice, where the push-out mechanism of the core solitons meets the resistance of a localized EMC Wall. This hypothesis could provide a more robust mechanical explanation for the stability of stars and the anomalous heating of the solar corona, interpreted here as a region of non-linear lattice relaxation and high-frequency nodal friction.

Hypothesis: Variable Vacuum Impedance in Stellar Media

It has been hypothesized that stars possess an EMC precursor wall. This local increase in $N_{\nu,\text{tmp}}$ would manifest itself as a measurable change in vacuum impedance, potentially altering the local speed of light. Unlike general relativity (GR), which attributes such delays to metric curvature, EWT theory proposes a mechanical slowdown caused by increased BCC lattice stiffness near the saturation point. It remains an open question how far from the stellar core such a precursor could exist and what magnitude of deflection it assumes.

Hypothesis: Residual EMC Walls and the Geometry of Weak Interactions

It is hypothesized that every matter soliton is bounded by a **residual or "degraded" EMC wall**, defined by a local density gradient $N_{\nu,\text{stat}} > x > N_{\nu,\text{eff}}$. While the soliton core represents a zone of vacuum exhaustion, its boundary serves as a high-impedance interface where the push-out mechanism meets the statutory background of the BCC lattice. This boundary layer can provide a physical site for weak interactions.

Hypothesis: The EMC Wall as a Dimensional Transformer ($\pi^6 \rightarrow \pi^7$)

It is hypothesized that the residual EMC wall acts as a dimensional interface. Within this gradient, the interaction scales from the **volumetric bosonic coupling** (π^6) to the **full charge density resonance** (π^7). In this view, the electric charge is not an intrinsic "point-property" but the highest dimensional manifestation of the soliton's engagement with the BCC lattice.

29.2 The Erasure of "Dark" Placeholders

The success of the structural EWT framework renders several foundational "mysteries" of the Standard Model obsolete. By grounding physics in the properties of the BCC lattice, we eliminate the following "dark" placeholders:

- **Dark Matter as a Geometric Push-Force:** Rather than invoking undiscovered WIMPs, EWT identifies galactic rotation anomalies as a consequence of the **massive EMC volume deficit**. The near-total geometric gap at the G -operating point creates a pervasive external pressure gradient that "pushes" matter toward regions of lower nodal density.
- **Dark Energy as Vacuum Static Pressure:** Accelerated expansion is reinterpreted as the **restorative elastic response** of the BCC lattice. "Dark Energy" is simply the

3660 statutory static pressure of the EMC background acting upon the structural voids created
3661 by matter solitons—the vacuum's "desire" to return to its statutory equilibrium.

3662 • **Virtual Particles and Loop Complexity:** The thousands of Feynman diagrams are
3663 replaced by the **Nodal Stiffness** N . Vacuum fluctuations are revealed to be the deter-
3664 ministic, high-frequency oscillations of the lattice nodes.

3665 • **The Hierarchy Problem:** The discrepancy between gravity and electromagnetism is a
3666 simple ratio: gravity is a statistical effect of **missing nodes** (EMC deficit), while electro-
3667 magnetism is a dynamic effect of **node workload** (energetic load ρ_E).

3668 29.3 Resolution of Historically "Unsolvable" Paradoxes

3669 The mechanical properties of the BCC lattice, combined with the threshold-based dynamics of
3670 the **EMC Wall**, provide deterministic solutions to several long-standing paradoxes that have
3671 remained unresolved within the probabilistic framework of the Standard Model.

3672 The Horizon Problem: Nodal Saturation and Thermalization

3673 The large-scale uniformity of the universe is a consequence of the **Initial Saturation State**.
3674 In the earliest epoch, the vacuum medium existed at the **Max Packing limit** ($N_{\nu,\max} \approx 10^{54}$),
3675 where the BCC lattice is structurally incompressible.

3676 In this state of maximal density, nodal stiffness is absolute, and the velocity of structural equi-
3677 librium is effectively infinite. This "Super-Statutory" phase allowed the entire medium to act
3678 as a single, coupled resonator, achieving perfect thermal uniformity. The subsequent relaxation
3679 of the lattice toward the **Statutory Limit** ($N_{\nu,\text{stat}}$) and eventually the current **Effective Op-**
3680 **erating Point** ($N_{\nu,\text{eff}}$) preserved this initial homogeneity, rendering the speculative "Inflation"
3681 field unnecessary.

3682 The Information Paradox: Nodal Memory

3683 The "loss" of information in a black hole is prevented by the physical nature of the event horizon.
3684 The **EMC Wall** acts as a high-density storage medium. The decomposition of matter at the
3685 boundary is not an erasure, but a **transduction**: the soliton's wave frequency is encoded into the
3686 **Nodal Memory** of the saturated BCC lattice ($N_{\nu,\max}$). Information is preserved as a specific
3687 vibrational state of the wall's nodes.

3688 The GZK Limit: Lattice-Induced Drag

3689 The Greisen-Zatsepin-Kuzmin (GZK) limit, which restricts the energy of cosmic rays, is revealed
3690 to be a **structural speed limit**. As a particle soliton approaches extreme energies, it creates
3691 a "Micro-EMC Wall" (a local compression wave) directly ahead of its path. This results in a
3692 non-linear increase in vacuum resistance, effectively capping the maximum energy a soliton can
3693 maintain while moving through the BCC substrate.

3694 Matter-Antimatter Asymmetry: Asymmetric Phase-Lattice Transition

3695 In the EWT framework, following the geometric interpretation proposed by Yee and Gardi [26],
3696 antimatter is defined as a soliton state characterized by a 180° (π) phase-shift. The observable
3697 dominance of matter is reinterpreted as a result of **Non-linear Phase Conversion** occurring
3698 at the **trans-statutory boundary** ($N > N_{\nu,\text{stat}}$) of EMC Walls.

In this model, the transition through an EMC Wall is not phase-symmetrical. While the wall acts as a resonant processor that can theoretically shift phases in both directions, the current G -operating point of the global BCC lattice creates a bias that favors "locking" solitons into the matter-phase. Consequently, antimatter is a phase that less frequently exits the high-EMC density regions in its original form, being resonantly re-tuned to the dominant background. This suggests that the universe's matter-bias is a dynamic equilibrium maintained by the lattice's tuning, where high-EMC density regions act as filters that preferentially stabilize the primary soliton phase.

29.4 Density Duality: From Local Refraction to Cosmological Redshift

The Energy Density Profile $\rho_E(\mathbf{r})$ as the Origin of Local Refractive Index and EM Wave Slowing

While the **geometric packing density function** $\rho(\mathbf{r})$ describes the non-uniform distribution of the elastic medium and is fundamental to the emergence of the gravitational constant G , a profound and distinct consequence of the Soliton's internal structure is the role of its **localized energy concentration** in the propagation of electromagnetic (EM) waves.

The hypothesis is presented that the local **energy density** $\rho_E(\mathbf{r})$ (which defines the Soliton's mass $E = mc^2$) acts as a local, variable refractive index for EM waves. The speed of light c is modified locally to $v(r)$ based on the energy density profile:

$$v(r) = \frac{c}{n(r)}, \quad n(r) \approx 1 + C_E \cdot \rho_E(r), \quad (285)$$

where C_E is a constant of proportionality related to the electromagnetic field coupling with the Soliton's high energy density.

Compatibility with Density Duality (Clear Separation of Roles). This change establishes clear and distinct physical roles:

- **Refraction:** The **high energy density** (ρ_E) ensures $n(r) > 1$ and correctly predicts the **slowing of EM waves** inside the Soliton/Matter.
- **Gravity:** The **low geometric packing density** ($\rho(\mathbf{r})$) remains solely responsible for the geometric deficit ($N_{\nu, \text{effective}}$), which drives the **push force gravity**.

This framework suggests that the fundamental mechanism for the **slowing of EM waves in matter** (refraction) is the interaction with the combined, non-uniform $\rho_E(\mathbf{r})$ profiles of the atomic constituents. The geometric parameter that governs gravitational weakness ($N_{\nu, \text{effective}}$, which is derived from the **integral of $\rho(\mathbf{r})$**) is thus linked to a core electromagnetic phenomenon (refraction) controlled by a **separate density component** (ρ_E).

Refractive index and Nodal Delay. The slowing of EM waves inside the Soliton is not a function of the number of nodes (geometric density $\rho(r)$), but the "workload" of each node (energy density ρ_E). While the massive deficit of EMC components (the gap between statutory and effective N_{ν}) drives the gravitational push-force, the nodes are subject to extreme oscillatory stress. This increases the **nodal response time**, effectively lowering the propagation velocity $v(r) = c/n(r)$ as a function of $\rho_E(r)$.

Cosmological Implications and the Geometric Origin of Redshift

The geometric derivation of $\mathbf{G}$ and the structural formalization of the Soliton ($\rho(\mathbf{r})$) carry profound consequences for cosmology. The EWT model fundamentally shifts the interpretation

of observed phenomena away from dynamic spacetime expansion toward **wave propagation dynamics within the Elastic Medium Constituent (EMC)**.

The concept of gravity as a **push force** resulting from the volume deficit (N_ν) suggests an alternative framework for the accelerating expansion of the universe. This expansion, typically attributed to Dark Energy, can be re-interpreted as the **external pressure of the EMC background** acting on regions of matter deficit.

Furthermore, the dual role of the Soliton's energy density ($\rho_E(\mathbf{r})$) in governing both mass and local EM wave slowing (refraction) opens the possibility that **cosmological redshift (z)** may be partially or entirely a consequence of **"tired light" effects**—minimal energy loss of EM waves due to interaction with the bulk properties or temporal evolution of the EMC background over vast distances.

Synthesis of Geometric and Temporal Properties: While ϵ_M defines the fundamental geometric permeability (stiffness) of the vacuum in solitons, the **Nodal Delay** represents the temporal manifestation of this stiffness when under energetic load (ρ_E). This unifies the EMC deficit (ρ) with the dynamic slowing of light (refraction) and the cumulative energy loss over cosmological distances (redshift). This perspective effectively replaces the notion of "empty space" with a dynamic, elastic medium whose response time is intrinsically coupled to its energy density.

Although this model focuses on leptonic structure, the unification of geometric parameters suggests that the Nodal Delay mechanism may have a cumulative component at the cosmological scale. This allows for the hypothesis of a non-Doppler origin for a portion of the redshift, representing a promising direction for future research into the nature of the EMC background.

30 Outlook and Computational Tools

The formal establishment of the Magneto-Geometric Hypotheses (Section 18) provides clear, testable predictions for the effective gravitational constant G (Section 26.3). Beyond direct experimental verification, the computational modelling of the Soliton geometry and its dynamic coupling to the Elastic Medium Constituent (EMC) is being pursued on the open-source platform **OpenWave** (<https://github.com/openwave-labs/openwave>).

Progress in the Scalar M3 Model

In the scalar Wolff-LaFreniere model (M3), a spherical-phyllotaxis (golden-angle, $\sim 137.5^\circ$) configuration of wave centres was implemented and tested as a proof-of-concept. The results provided the first in-platform demonstration that a spherical, minimally interfering geometry can create K-selectivity: only $K_{WC} = 10$ formed a stable standing wave, while $K_{WC} = 9$ and $K_{WC} = 11$ decayed systematically. This validated the underlying principle that phyllotactic packing suppresses destructive interference, a principle that will be essential for the high-multiplicity recursive shells of the muon and tau. For the electron core itself, the native EWT topology (1-3-6 tetrahedron) remains the physically required configuration, as it alone guarantees the correct multipole structure for far-field forces. The golden-angle module, together with the logged simulation data, is available in the `m3_wolff_lafreniere` directory of the OpenWave repository.

Diagnostics in the Vector M4 Model and Implementation Plan

The same golden-angle arrangement does *not* stabilise the electron core in the vector model M4 (neither with nor without an initial spin), indicating that the missing ingredient in M4 is not geometric but nonlinear. The immediate goal is to stabilise the native 1-3-6 electron topology by

introducing the nonlinear self-trapping term derived in Section 25. Once the electron core is stable with its proper geometry, the golden-angle phyllotaxis will be applied to the high-multiplicity recursive shells of the muon and tau, where it is expected to be indispensable. Consequently, the following implementation roadmap has been adopted:

1. **Nonlinear term $\mathcal{F}(\Psi)$:** A cubic self-trapping term $\gamma \Psi^3$ will be added to the M4 wave kernel, with the coupling coefficient $\gamma = 1/\epsilon_M = N_{\text{final}}\pi^3 \approx 2.41 \times 10^4$ derived from the BCC geometry.
2. **Degraded EMC Wall:** A radial density gradient will be introduced to suppress shear instabilities and to provide a natural boundary where the phyllotaxis can later be introduced for the outer shells.
3. **Validation:** Once the nonlinearity is in place, the native EWT topology (1-3-6 tetrahedron) will be tested for K-selectivity.
4. **Shell application:** After the core is stabilised, the golden-angle arrangement will be deployed for the muon and tau shells.

Connection to the Nonlinear Stability Equation

A sketch of the required nonlinear wave equation was proposed in part by the OpenWave team during the collaborative development of the M3 and M4 engines. Building on that foundation, a formal nonlinear wave equation that guarantees the electron's stability is derived in Section 25, where the geometric constants ϵ_M and $\gamma = 1/\epsilon_M$ determine the self-trapping term. The full implementation of this equation in the OpenWave M4 kernel is the immediate next step.

This computational framework serves as a **theoretical complement to physical experiments**, allowing rapid iteration and falsification of the Soliton's micro-geometric constraints within the EWT Model.

31 Conclusion: The Geometric Paradigm, Correlated Lepton Anomalies, and Emergent Gravity

The formalization within the Energy Wave Theory establishes the **Minimal Wave Center** — the Neutrino Soliton — as a fundamental geometric structure. The central finding of this work is the derivation of the gravitational constant G as a geometric identity, together with the prediction of the lepton anomalous magnetic moments from the same underlying BCC lattice parameters. This necessitates a critical re-evaluation of the Soliton's geometric parameters.

This achievement realizes a principle that is increasingly recognized as a necessity for resolving the deepest tensions in modern physics. As highlighted by the CosmoVerse Network [48], addressing the observational crises in cosmology may ultimately require abandoning the notion of rigid, immutable fundamental constants in favour of dynamic, relational parameters. The Enhanced EWT model does not merely accommodate this principle; it provides its precise geometric mechanism. The observed “constants” — the gravitational coupling G , the electromagnetic coupling α , and the electron anomalous magnetic moment a_e — are not independent inputs but are scale-dependent projections of a single invariant: the structural impedance of the BCC vacuum lattice.

For the muon and tau generations, the model presently derives the anomalous magnetic moments as genuine predictions of the BCC lattice geometry, while the reference scale for comparison is obtained from the orbital mass relations. This constitutes a high-precision internal

3824 consistency test between the geometric and mass-generation sectors; the simultaneous, fully in-
 3825 dependent derivation of both mass and AMM for all generations remains an open objective.

3826 **Constants are not constant; only the relations between them are.**
 This relation, dictated by the fixed topology of the vacuum substrate, is the true
 fundamental law from which all measurable quantities emerge.

3827 31.1 Geometric Unification in a Nutshell: The ϵ_M Flowchart

3828 The Enhanced EWT Model operates on the principle of **Structural Monism**: all fundamental
 3829 coupling constants are derived from the same vacuum stiffness deficit. Rather than treating grav-
 3830 itation, electromagnetism, and lepton anomalies as independent phenomena, they are expressed
 3831 as direct geometric functions of the primary modulator ϵ_M .

$$\epsilon_M \Rightarrow \begin{cases} \mathbf{G} = \frac{\mathbf{G}_{\text{Base}}}{A_\pi} \cdot \left(\frac{\epsilon_M \cdot \pi^3}{A_\pi} \right)^3 \cdot \frac{1}{K_{WC} \cdot \sqrt{N_{\nu, \text{eff}}}} & \text{(Gravitational Scale)} \\ \alpha_{\text{geom}}^{-1} = A_\pi - \epsilon_M & \text{(Electromagnetic Scaling)} \\ a_e = \frac{\alpha_{\text{geom}}}{2\pi} \cdot (1 - \epsilon_M \cdot \pi^3) & \text{(Nodal Magnetic Deficit)} \\ C_{\text{local}} = \frac{\epsilon_M}{2\sqrt{2}} & \text{(Geometric Seed for Mixing Hierarchy)} \\ R_l = \text{recursive}(\epsilon_M, L_{\text{Fib}}) & \text{(Leptonic Shell Resonance)} \end{cases} \quad (286)$$

3832 In this zero-calibration formulation,

$$\epsilon_M = \frac{1}{N_{\text{geom}} \pi^3} = \frac{1}{8\pi^7(1 - \zeta)}, \quad (287)$$

3833 where $N_{\text{geom}} = 8\pi^4(1 - \zeta)$ is the effective geometric stiffness and ζ is the BCC packing impedance.

3834 31.2 The Unitary Geometric Path

3835 As illustrated in the schematic, ϵ_M acts as the **Universal Gear Ratio** of the vacuum lattice.
 3836 A single modulator simultaneously determines:

- 3837 • the gravitational coupling G ,
- 3838 • the electromagnetic coupling α_{geom} ,
- 3839 • the damping of the magnetic precession across generations, yielding a_e, a_μ, a_τ .

3840 This flowchart confirms that the Enhanced EWT Model is not a collection of independent
 3841 equations, but a **Unitary Geometric Circuit**. Any change in the value of ϵ_M would simulta-
 3842 neously shift all fundamental constants derived from it.

3843 31.3 The Geometry of the Constituent: From Cubic Grids to Spherical 3844 Units

3845 While the initial formalization of the EWT lattice utilizes the Body-Centered Cubic framework
 3846 for its nodal efficiency, the physical reality of the **Elastic Medium Constituent** is fundamen-

3847 tally spherical. This transition from a “cubic cell” to a “spherical grain” is a natural consequence
 3848 of the model’s convergence toward a minimum energy state and isotropic wave propagation.

3849 **Packing Fraction and the Vacuum Void**

3850 In a BCC lattice composed of hard spherical constituents, the maximum packing factor is

$$\eta_{\text{BCC}} = \frac{\sqrt{3}\pi}{8} \approx 0.680. \quad (288)$$

3851 This inherent geometric property implies that:

- 3852 • The vacuum is not a continuous “solid block” but a structured, granular medium with a
 3853 defined interstitial capacity.
- 3854 • The volume deficit N_ν identified in the gravitational derivation represents the displacement
 3855 of these spherical units.
- 3856 • The spherical nature of the EMC ensures isotropic nodal stiffness.

3857 **The Transition of Density Levels**

3858 The granular nature of the EMC directly dictates the three levels of vacuum density identified
 3859 in the EWT hierarchy:

- 3860 • **Maximum packing:** $N_{\nu,\text{max}} \approx 5.30 \times 10^{54}$.
- 3861 • **Statutory background:** $N_{\nu,\text{stat}} \approx 3.30 \times 10^{52}$.
- 3862 • **Effective gravitational density:** $N_{\nu,\text{eff}} \approx 6.25 \times 10^{48}$.

3863 **31.4 Pillar 1: The N_ν Deficit and Soliton Stability**

3864 A cornerstone of the EWT model is the derivation of the gravitational constant G from the
 3865 microscopic geometry of the neutrino soliton and the electron soliton. In the zero-calibration
 3866 formulation, the transition from the statutory background to the effective density is governed by
 3867 the geometric dilution factor X_{eff} :

$$N_{\nu,\text{eff}} = \frac{N_{\nu,\text{stat}}}{X_{\text{eff}}}, \quad (289)$$

3868 where X_{eff} is fixed by A_π , $K_{WC} = 10$, and the ideal BCC projection factor $L_p^{\text{geom}} = 2/\sqrt{3}$.
 3869 The resulting density hierarchy is:

$$\rho_{\text{eff}} < \rho_{\text{stat}} < \rho_{\text{max}}. \quad (290)$$

3870 Macroscopic gravitational attraction is the response of the external, higher-density vacuum
 3871 medium ($N_{\nu,\text{stat}}$) attempting to restore equilibrium by pressing toward the lower-density soliton
 3872 core.

31.5 Pillar 2: The Dynamic Scaling Operator Ω_{Push}

The dynamic push-out operator,

$$\Omega_{\text{Push}} \equiv G_{\text{Base}} \cdot A_{\pi}^{-1} \cdot (N_{\text{geom}} A_{\pi})^{-3}, \quad (291)$$

is the central mechanism in the G equation.

The final gravitational identity is:

$$G \equiv \underbrace{G_{\text{Base}} \cdot \frac{1}{A_{\pi}} \cdot \left(\frac{1}{N_{\text{geom}} A_{\pi}} \right)^3}_{\Omega_{\text{Push}}} \cdot \underbrace{\frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}}}_{T_{\text{Surface}}}. \quad (292)$$

The factor $\epsilon_M = (N_{\text{geom}} \pi^3)^{-1}$ is the master key of this operator. It dictates both the gravitational scale and the lepton anomalous magnetic moments.

31.6 Pillar 3: The Recursive Paradigm — Hierarchical Nodal Integration

The transition from the electron core to the muon and tau generations is viewed as a hierarchical integration of nested nodal shells, anchored by the Fibonacci invariants

$$L_{\mu} = 5, \quad L_{\tau} = 34. \quad (293)$$

The full AMM predictions are:

$$a_e^{\text{EWT}} = 1.159916 \times 10^{-3}, \quad a_{\mu}^{\text{EWT}} = 1.166213 \times 10^{-3}, \quad a_{\tau}^{\text{EWT}} = 1.176838 \times 10^{-3}. \quad (294)$$

The recursive architecture replaces the perturbative loop paradigm of the Standard Model with a single unified geometric identity.

31.7 The Soliton Radius and Neutrino Interaction Cross-Section

A common concern regarding geometric particle models is the apparent tension between a comparatively large geometric radius and the extremely small neutrino interaction cross-sections. This model resolves the issue by distinguishing between:

- the **geometric soliton radius** r_{geom} ,
- the **interaction cross-section** σ_{ν} .

The weakness of the neutrino interaction reflects the fact that only a minute fraction of the soliton's internal energy is available at its boundary for weak interactions. This dilution is quantified by the effective volume deficit:

$$\sigma_{\nu} \propto \frac{1}{N_{\nu, \text{eff}}}, \quad (295)$$

so that even a soliton with a substantial geometric radius can possess an exceedingly small interaction cross-section.

31.8 Paradigm Shift: The Planck Length as a Physical Boundary

In EWT, the Planck length is assigned a definitive physical and geometric role: it is the approximate magnitude of the base quantum distance λ_l , which defines the physical separation of the Elastic Medium Constituents.

In this framework, λ_l is not an external input; it is the self-consistent geometric Planck length derived in Section 11.6. All physics operates consistently at and above this scale, allowing the direct geometric calculation of macroscopic constants like G and α .

31.9 The ϵ_M Factor: Universal Geometric Modulator

The core tenet of EWT is that mass, charge, and spin are manifestations of the Soliton's wave geometry. The unified role of the magnetic deficit factor is governed by a fundamental geometric duality: while the Soliton's internal energy storage follows $E \propto r^5$, the volume of the displaced elastic medium follows $V \propto r^3$.

The factor ϵ_M acts as the universal modulator that reconciles these two scaling laws. It performs three distinct functions:

1. **Gravity:** It scales the volumetric deficit to the observed gravitational constant G .
2. **Electromagnetism:** It bridges the gap between α_{geom} and the soliton core.
3. **Spin/AMM:** It defines the recursive nodal integration of lepton anomalies.

The necessity of using the same factor ϵ_M across all these domains is the definitive proof of geometric unification.

31.10 Geometric Self-Consistency of the Planck–Gravity–Metric Triangle

A central result of the present work is the recognition that G_{geom} , $\hbar_{\text{geom}}$, λ_l , and c do not form a hierarchy of independent constants. They are linked by the closed geometric condition

$$\lambda_l = \sqrt{\frac{\hbar_{\text{geom}} G_{\text{geom}}}{c^3}}, \quad (296)$$

where

$$\hbar_{\text{geom}} = \frac{m_e c r_e}{\alpha_{\text{geom}}}, \quad G_{\text{geom}} = \frac{G_{\text{Base}}}{A_\pi} \left(\frac{1}{N_{\text{geom}} A_\pi} \right)^3 \frac{1}{K_{WC} \sqrt{N_{\nu, \text{eff}}}}. \quad (297)$$

The effective density $N_{\nu, \text{eff}}$ itself depends on λ_l through the statutory background,

$$N_{\nu, \text{eff}} = \frac{1}{X_{\text{eff}}} \left(\frac{r_\nu}{2e\lambda_l} \right)^3. \quad (298)$$

Thus Eq. (296) is not a definition imported from outside the model. It is an internal algebraic constraint that simultaneously fixes the gravitational scale, the quantum scale, and the fundamental lattice spacing from the same BCC geometry.

In natural units ($c = 1$), this constraint reduces to the purely geometric statement

$$\lambda_l^2 = \hbar_{\text{geom}} G_{\text{geom}}, \quad (299)$$

3926 showing that the square of the fundamental EMC length is the product of the geometric quantum
 3927 of action and the geometric gravitational coupling.

3928 This closure is a direct consequence of the BCC lattice structure. It is not an import from the
 3929 Standard Model: the Planck scale, the reduced Planck constant, and the gravitational constant
 3930 are reconstructed here as derived quantities, not assumed inputs.

3931 **31.11 Final Synthesis**

3932 The Enhanced EWT model demonstrates that the fundamental constants are integrated reso-
 3933 nances of a single BCC substrate. The geometric vacuum stiffness N_{geom} , the magnetic deficit
 3934 ϵ_M , and the geometric core A_π together determine the fine-structure constant, the gravitational
 3935 constant, the lepton anomalous magnetic moments, and the principal atomic scales.

3936 The model is not claimed to be absolutely parameter-free. It currently uses four experimental
 3937 anchors:

$$r_e, \quad m_e, \quad c, \quad e. \quad (300)$$

3938 These anchors are fixed by measurement and by the metric convention. They are not adjustable
 3939 calibration parameters: if any one of them were changed independently while keeping the BCC
 3940 geometry fixed, the entire set of geometric predictions would break. The model therefore contains
 3941 no free calibration constants; it is zero-free-parameter in the operational sense.

3942 Of these anchors, c is a metric conversion factor rather than a dynamical parameter. The
 3943 electron mass m_e may also be derivable in the future through the $E \propto r^5$ scaling law and the
 3944 $K_{WC} = 10$ stability condition. The true irreducible anchors would then reduce to r_e and e .
 3945 electromagnetism, and the lepton hierarchy.

3946

A Appendix

3947

A.1 List of Model Parameters and Physical Constants

3948

3949

3950

3951

The following table lists the fundamental physical constants and key dimensionless geometric factors used in the Geometric Soliton Model. The numerical consistency of the model relies on the exact values shown below, combining CODATA 2022 constants with the derived EWT geometric parameters.

Table 22: **EWT Parameters and CODATA 2022 Values Used in the Geometric Derivations**

Parameter	Symbol	Numerical Value	Source / Justification
I. Fundamental Constants (CODATA 2022)			
Speed of Light	c	299792458	Defined constant (m/s).
Electron Mass	m_e	$9.1093837015 \times 10^{-31}$	CODATA 2022 reference (kg).
Classical Radius	r_e	$2.8179403262 \times 10^{-15}$	CODATA 2022 reference (m).
II. Hierarchical Volume Deficit Parameters			
Absolute Maximum	$N_{\nu,\max}$	5.3004×10^{54}	Theoretical EMC packing limit.
Statutory Background	$N_{\nu,\text{stat}}$	3.2986×10^{52}	Eulerian vacuum capacity.
Effective Deficit	$N_{\nu,\text{eff}}$	6.2472×10^{48}	Integrated Soliton density.
Geometric Bridge Operator	X_{eff}	5275.7683	Transforms $N_{\nu,\text{stat}}$ into $N_{\nu,\text{eff}}$.
III. Geometric Operators			
Geometric Base	A_π	137.0363037759	$4\pi^3 + \pi^2 + \pi$. Static foundation.
Effective Stiffness	N_{geom}	778.8025179	$8\pi^4(1 - \zeta)$.
Lattice Impedance	ζ	0.0006033964	From BCC packing fraction.
Magnetic Deficit	ϵ_M	$4.141169769 \times 10^{-5}$	$1/(N_{\text{geom}}\pi^3)$.
Lattice Projection	L_p^{geom}	1.1547005384	$2/\sqrt{3}$, ideal BCC projection.
Unified Coupling	C_{unif}	1.1020116168	Using L_p^{geom} .

A.2 Computational Scripts (Python)

All numerical results in this work are produced by a set of Python scripts that implement the zero-calibration geometric model described in the main text. The scripts are self-contained and use only standard scientific libraries. The source code and console outputs are listed below. Persistent identifiers for each script will be added in the final published version.

A.2.1 Emergence Engine

`ewt_emergence_engine.py` is the core geometric engine. It derives the fine-structure constant, magnetic deficit, neutrino radius, Planck length, gravitational constant, lepton anomalous magnetic moments, and atomic scales from the BCC lattice geometry. The script also performs the rigidity tests described in Section 28.

# SECTION 1: GLOBAL INPUTS & CONSTANTS
# -----
# This section contains:
#   - mathematical constants
#   - experimental reference values (CODATA 2022 / PDG 2022)
#   - pure BCC lattice geometry (independent of the EWT model)
#
# Every quantity is explicitly labelled:
#   INPUT      : experimental value used as an anchor or metric input
#   MATHEMATICAL : pure mathematical constant
#   BCC_GEOMETRY : crystallographic fact about the BCC lattice
#
# The model itself will not define any additional hidden numerical parameters
# in this section. All later parameters must be either DERIVED, POSTULATED,
# or explicitly marked as CALIBRATION (to be eliminated in future versions).
# =====

A.2.5 AMM Resonance Scanner

ewt_amm_resonance_scanner.py scans the (K_μ, K_τ) nodal-count space and identifies the resonance minima. It also generates the PDF figures used in the sensitivity analysis.

```
#!/usr/bin/env python3
"""
From manuscript version: 5.0.0

Enhanced EWT -- AMM Resonance Scanner (Onion Model)
=====
Python port of the Scilab AMM_find.sc script, adapted to the
zero-calibration geometric eps_M from BCC packing impedance.

Scans the (K_muon, K_tau) space and identifies resonance points
with minimal internal error against the EWT shell references.

Generates:
    Fig1_Muon_Profile.pdf
    Fig2_Tau_Profile.pdf
    Fig3_3D_Peak.pdf
    Fig4_Topography.pdf

A.2.8 Electroweak and Boson Module Output

The console output of `ewt_electroweak_bosons.py` is reproduced below.

```

6032 EWT ELECTROWEAK & BOSON MODULE
6033
6034
6035 --- WEINBERG SECTOR ---
6036   EWT Predicted W-Boson Mass:      80.5141 GeV
6037   CDF II Experimental Target:      80.4335 GeV
6038   Percentage Error vs. CDF II:     0.1002 %
6039
6040 --- EWT SPHERICAL MODE MASSES ---
6041   Z boson (K=110): 91.7313627983 GeV
6042   Higgs (K=117): 124.9613469754 GeV
6043
6044 --- HIGGS MIXING PREDICTIONS ---
6045   Higgs-Z Mixing  $\sin^2(\theta_{ZH})$ : 0.4686094602
6046   Higgs-W Mixing  $\sin^2(\theta_{WH})$ : 0.5906241192
6047   Note: ZH stability is superior due to the neutrality of Z and H solitons.
6048
6049 --- WEINBERG ANGLE TEST (EWT spherical masses) ---
6050   M_Z = 91.7313627983 GeV, M_W = 80.5141221669 GeV
6051   Predicted  $\sin^2(\theta_W)$  = 0.2403072946
6052   Experimental      = 0.23122
6053   Relative error    = 3.930151 %
6054
6055 --- WEINBERG ANGLE TEST (empirical masses) ---
6056   M_Z = 91.1876000000 GeV, M_W = 80.4335000000 GeV
6057   Predicted  $\sin^2(\theta_W)$  = 0.2327588525
6058   Experimental      = 0.23122
6059   Relative error    = 0.665536 %
6060
6061 --- HEAVY BOSON GEOMETRIC RADIUS PREDICTIONS ---
6062   Z-Boson (K=110) Predicted Radius: 3.1677478423e-14 m
6063   Higgs (K=117) Predicted Radius: 3.3697848561e-14 m
6064   VERIFICATION AGAINST NUCLEAR SCALES:
6065   Predictions match the 10-14 m order of magnitude, consistent
6066   with the mass-equivalent isotopes (Mo-98 and Xe-134).
6067
6068 --- CABIBBO MIXING & SURFACE RESONANCE ---
6069   C_fermion ( $\pi^5$  operator):      1.0089810940
6070   VARIANT A: EWT-derived quark masses (spherical mode)
6071     EWT d-quark mass (K=15):      0.0040343942 GeV
6072     EWT s-quark mass (K=28):      0.0948854322 GeV
6073     EWT Prediction  $\sin(\theta_C)$ : 0.2080522521
6074     PDG 2022 Target:              0.2243000000
6075     Percentage Error:              7.243757 %
6076   VARIANT B: PDG 2022 target quark masses (mechanism test)
6077     PDG d-quark mass:              0.0046920000 GeV
6078     PDG s-quark mass:              0.0949540000 GeV
6079     EWT Prediction  $\sin(\theta_C)$ : 0.2242876694
6080     PDG 2022 Target:              0.2243000000
6081     Percentage Error:              0.005497 %
6082   INTERPRETATION:
6083   Variant A error originates from EWT light quark mass predictions.
6084   Variant B isolates the geometric mixing mechanism ( $\pi^5$  operator).

```

Listing 8: Console output from `ewt_electroweak_bosons.py`.

A.2.9 Particle Mass Module

`ewt_particle_masses.py` implements the spherical, orbital, and meson mass modes and performs the full PDG/CODATA mass scan.

```

6500 A.2.11 Robustness and Stability Plots

6501 `ewt_robustness_plots.py` generates the stability figures used in Section 28, including the G
6502 surface transition, alpha sensitivity, phase-space trajectory, point-lock convergence, and AMM
6503 robustness curves.

6509 =====
6510 Python port of EWT_Robustness_G_AMM_check.sc (Modules 1-10),
6511 adapted to the zero-calibration geometric version.
6512
6513 Uses the geometric eps_M derived from BCC packing impedance
6514

```

```

6515 instead of the old calibrated N_final and L_p.
6516
6517 Generates the same PDF figures as the Scilab original.

7056 Statements and Declarations

7057 **Funding:** The author declares that no funds, grants, or other support were received during the
7058 preparation of this manuscript.

7059 **Competing Interests:** The author has no relevant financial or non-financial interests to
7060 disclose.

7061 **Author Contributions:** Ł. Smoliński is the sole author of this manuscript, responsible for
7062 the conceptualization, methodology, formal analysis, and writing.

7063 **Data and Code Availability:** The complete repository for Project MagnetismGravity is
7064 openly accessible to support scientific reproducibility:

- 7065 • **Datasets:** The EWT core dataset is available on Hugging Face: <https://huggingface.co/datasets/luksmol/EWT-Vacuum-Lattice-Unified-Physics/tree/main>.
- 7067 • **Interactive Auditor:** The web-based EWT Auditor application is deployed at: <https://huggingface.co/spaces/luksmol/EWTAuditor>.
- 7069 • **Version Control:** The active development source code is maintained on GitHub: <https://github.com/lsmolinski/MagnetismGravity>.

Final Remark

The history of physics teaches us that the path to unification often lies within the most fundamental constituents of nature. Just as the quest to fully understand the electron once held the promise of unraveling quantum electrodynamics, the evidence presented in this geometric, unified model points to a more profound truth. By demonstrating that the neutrino's inherent wave geometry is the common source of the gravitational constant $\mathbf{G}$, the fine-structure constant α , and the anomalous magnetic moments, the picture is also completed by the discovery of the Weinberg and Cabibbo angles as the structural resonance limits of the vacuum lattice. The conclusion is inescapable: **It would have been enough to understand the neutrino.**
